28

29 **ABSTRACT:** The olive-knot disease (*Olea europea* L.) is caused by the bacterium  
30 *Pseudomonas savastanoi* pv. *savastanoi* (PSV). PSV in the olive-knot undergoes  
31 interspecies interactions with the harmless endophyte *Erwinia toletana* (ET); PSV and ET  
32 co-localize and form a stable community resulting in a more aggressive disease. PSV and  
33 ET produce the same type of the *N*-acylhomoserine lactone (AHL) quorum sensing (QS)  
34 signal and they share AHLs in planta. In this work we have further studied the AHL QS  
35 systems of PSV and ET in order to determine possible molecular mechanism(s) involved  
36 in this bacterial inter-species interaction/cooperation. The AHL QS regulons of PSV and  
37 ET were determined allowing the identification of several QS-regulated genes.  
38 Surprisingly, the PSV QS regulon consisted of only a few loci whereas in ET many  
39 putative metabolic genes were regulated by QS among which several involved in  
40 carbohydrate metabolism. One of these loci was the aldolase-encoding gene *garL*, which  
41 resulted to be essential for both co-localization of PSV and ET cells inside olive knots as  
42 well as knot development. This study further highlighted that pathogens can cooperate  
43 with commensal members of the plant microbiome.

44 **SIGNIFICANCE OF THIS STUDY:** This is a report on studies of the quorum sensing  
45 (QS) systems of olive knot pathogen *Pseudomonas savastanoi* pv. *savastanoi* and olive-  
46 knot cooperator *Erwinia toletana*. These two bacterial species form a stable community  
47 in the olive knot, share QS signals and cooperate resulting in a more aggressive disease.  
48 In this work we further studied the QS systems by determining their regulons as well  
49 studying QS-regulated genes which might play a role in this cooperation. This represents  
50 a unique in vivo interspecies bacterial virulence model and highlights the importance of  
51 bacterial interspecies interaction in disease.

52

53 **INTRODUCTION**

54 The recent dramatic increase of microbiome studies has further evidenced what  
55 microbiologists have postulated for many years, that most commonly, microorganisms in  
56 nature live as members of complex multispecies communities (1, 2). This has  
57 demonstrated that many different microbes live in close proximity to each other; however,  
58 aspects of microbe-microbe interactions have thus far been significantly understudied. In  
59 addition, multispecies microbial communities existing in association with plants could be  
60 influenced by the plant and/or could have consequences on plant health; again very few  
61 studies have investigated this likely scenario.

62 Many bacterial species have been studied for their intraspecies signaling system which is  
63 known as quorum sensing (QS) (3). QS involves the production and detection of signal  
64 molecules which results in the regulation of gene expression in response to bacterial cell  
65 number/density (4). Gram-negative bacteria most commonly use *N*-acylhomoserine  
66 lactones (AHLs) as QS signals and in proteobacterial phytopathogens it is involved in the  
67 regulation of expression of virulence associated factors in the plant (5-9). An archetypical  
68 AHL QS system consists of a LuxI-family AHL synthase and a LuxR-family  
69 transcription factor which affects target gene expression upon interaction with the  
70 cognate AHL at quorum concentrations (10). AHLs vary in their structure having  
71 different acyl chain lengths (from 4 to 20 carbons) and display differences in their  
72 oxidation state at position C3. AHL signals can also be involved in interspecies signaling  
73 in a community since they are freely diffusible and can thus be detected by different  
74 bacterial neighbors. In bacterial pathogenesis, especially in human hosts, it is now

75 becoming recognized that many pathogens interact with other microorganisms which  
76 may influence the disease process (11-13).

77 Plant microbial diseases are however still very much considered as being caused by  
78 single pure pathogens; nevertheless evidence is also beginning to grow that there can be  
79 synergisms between different microorganisms. Recently, a clear example of such  
80 synergism has been reported in the olive-knot disease of olive trees (*Olea europea* L.)  
81 caused by the bacterium *Pseudomonas savastanoi* pv. *savastanoi* (PSV) (14, 15). PSV  
82 possesses a typical LuxI/R AHL QS system and it is involved in virulence since mutants  
83 in this system result in significantly smaller knots (15). The bacterial load of the knots  
84 (also called tumors) is 50% composed of PSV but also contain a significant proportion of  
85 an apparently harmless commensal multispecies bacterial community (16) and some  
86 members have been shown to cooperate with PSV resulting in an increase of disease  
87 severity (15). More precisely, an *Erwinia toletana* (ET) strain (harmless to the olive  
88 plant) isolated from the olive knot increased disease severity (larger olive-knot) when co-  
89 inoculated with PSV. In addition, it was demonstrated that ET, *Pantoea agglomerans* and  
90 PSV form stable multispecies communities and that they share and communicate via  
91 AHLs. Interestingly, ET and PSV synthesize structurally identical AHLs and co-  
92 inoculation experiments have evidenced that *E. toletana* can rescue AHL negative  
93 mutants of PSV and restore virulence (15). Microscopy studies have also revealed that  
94 ET and PSV co-localize in the olive-knot further indicating that the two species are  
95 sharing the same niche both benefiting from this stable interaction. In addition, *in silico*  
96 recreation of the biochemical metabolic pathways encoded by PSV and ET genomes  
97 suggested that metabolic complementarity and/or sharing of metabolites could be

98 involved in the beneficial interaction established between these two bacterial species (16).  
99 In this work we have further studied the AHL QS systems of PSV and ET, both *in vitro*  
100 and *in planta*, in order to identify specific molecular determinants involved in this  
101 interspecies bacterial interaction. Determination of the PSV and ET QS regulon allowed  
102 the identification of several QS-regulated genes putatively involved in numerous  
103 metabolic pathways, including the ET aldolase-encoding gene *garL*, which resulted to be  
104 essential for both co-localization of PSV and ET cells inside olive knots and full knot  
105 development.

106

107

108

109 **RESULTS**

110 **The *luxI/R* quorum sensing genes in *Pseudomonas savastanoi* pv. *savastanoi* NCPPB**  
111 **3335 and *Erwinia toletana* DAPP-PG 735**

112 The olive knot pathogen *Pseudomonas savastanoi* pv. *savastanoi* (PSV) NCPPB 3335  
113 (17, 18) was the first PSV genome sequenced and has been used in several studies of  
114 virulence mechanisms (19). This genome harbors a canonical *luxI/luxR* pair identical to  
115 the previously reported *pssI/R* QS system of PSV DAPP-PG 722 [hereafter named  
116 *pssI/pssR*; (15)] and two *luxR* solos which do not have a cognate *luxI* partner (Figure 1A).  
117 From the primary structure of the two LuxR solos, one likely responds to plant signals  
118 (designated as LuxR2) and the other most likely to AHLs (designated as LuxR3) (20, 21).  
119 Interestingly, this content of LuxI/R QS elements is conserved in all *P. savastanoi* strains  
120 infecting woody plants whose genomes have been sequenced (22-25).

121 With respect to the olive knot resident and PSV cooperator *E. toletana* (ET), we  
122 previously reported that ET DAPP-PG 735 was able to synthesize AHLs via the *EtoI/R*  
123 QS system. The *etoI* mutant, hereafter ETETOI, resulted in no AHL production hence it  
124 was concluded that ET possessed one AHL QS system (15). Sequencing of the ET  
125 genome (26) and its analysis performed here, surprisingly revealed that ET possessed a  
126 second complete canonical AHL QS system. The AHL-responsive transcriptional  
127 regulator gene was designated as *tolR* and the autoinducer synthase as *tolI* (Figure 1B).

128 **AHL production by *Pseudomonas savastanoi* pv. *savastanoi* NCPPB 3335 and**  
129 ***Erwinia toletana* DAPP-PG 735**

130 QS and AHL production by PSV NCPPB 3335 has not been addressed so far, thus a *pssI*  
131 mutant and its complemented strain, expressing the *pssI* gene from a plasmid, were

132 constructed. PSV NCPPB 3335, the *pssI* mutant and its complemented strain were grown  
133 overnight in LB broth and AHLs were extracted from spent supernatants as described in  
134 the materials and methods section. C6-AHL production was observed and determined for  
135 PSV NCPPB 3335, whereas no AHL production was detected for the  $\Delta pssI$  mutant strain  
136 (Table 4 and S1). Interestingly, four types of AHLs (C6-, C8-, 3-oxo-C6- and 3-oxo-C8-  
137 AHLs) were identified in the supernatant of the  $\Delta pssI$  complemented strain, indicating  
138 that overexpression of *pssI* leads to the production of some types of AHLs not detected in  
139 the wild type.

140 We also analyzed AHL production by the EtoI/EtoR and TolI/TolR ET DAPP-PG 735  
141 QS systems. Production of six types of AHL was detected for the wild type ET DAPP-  
142 PG 735: 3-oxo-C6-, 3-oxo-C8-, 3-oxo-C10-, C6-, C8- and 3-OH-C6-AHLs (Table 4 and  
143 S1). We previously reported that this ET strain produced 3-oxo-C6- and 3-oxo-C8-AHLs  
144 [15], thus this analytical chemical analysis revealed a wider spectrum of AHL production.  
145 As expected, the ETETOI mutant was unable to produce any type of AHL, while the  
146 ETETOI complemented strain restored the biosynthesis of all types of AHLs (Table 4  
147 and S1). The ETTOLI showed a defect in the biosynthesis of 3-oxo-C10-AHL and  
148 unexpectedly it was not restored via the expression of *tolI* in trans. The summary of the  
149 complete AHL analysis in relation to the peak areas of the detected chromatographic  
150 peaks are provided in Table S1 and Figure S3.

#### 151 **Transcriptional analysis of quorum sensing genes in PSV NCPPB 3335 and ET** 152 **DAPP-PG 735**

153 We previously observed that a *pssR* mutant of PSV DAPP-PG 722 produced an amount  
154 of AHLs similar to the wild type strain, suggesting that the positive feedback loop typical

155 of AHL QS systems does not occur in PSV. To address this possibility in PSV NCPPB  
156 3335, the *pssI* promoter region was cloned in a promoter probe vector (pMP220)  
157 upstream a promoterless *lacZ* gene and  $\beta$ -galactosidase activity was measured in PSV  
158 NCPPB 3335 and its derivative *pssI* and *pssR* mutants during their growth. As shown in  
159 Figure 2A, the activity of *pssI* promoter was significantly increased in the stationary  
160 phase (10 hours incubation) compared to the exponential phase (4 hours incubation) in all  
161 three PSV genetic backgrounds. Moreover, no differences in  $\beta$ -galactosidase activity was  
162 observed among the three strains in neither log phase nor stationary phase, thus  
163 confirming that the typical AHL QS positive feedback loop does not occur in PSV  
164 NCPPB 3335.

165 It was also of interest to study the expression of the ET QS systems; gene promoters of  
166 *etoI*, *etoR*, *toll* and *tolR* were fused to a promoterless *gfp* to perform a comparative *in*  
167 *vitro* transcriptional analysis of both systems in ET, ETETOI and ETTOLI genetic  
168 backgrounds. Results showed that *toll* and *tolR* genes had considerably lower promoters  
169 activities in ET compared to the *etoI* and *etoR* promoters (Figure 2B). Additionally,  
170 transcription of *etoR* in ETTOLI was enhanced compared to ET and ETETOI, suggesting  
171 that the Toll/TolR system might repress *etoR* transcription. Taking into account the low  
172 activity of *toll/tolR* promoters under the *in vitro* conditions used, we questioned if this  
173 system was activated *in planta*. To examine this possibility, co-inoculation of PSV with  
174 ET wild type harboring *toll* promoter fused to GFP were carried out in micropropagated  
175 olive plants. No GFP fluorescence was detected for *toll* promoter, whereas it was  
176 observed in the *etoI* promoter fusion, thus demonstrating that *toll* gene expression was  
177 very low also *in planta*. We then decided to perform a comparative analysis by RT-qPCR

178 of the transcription of *toll* and *tolR* genes in two different media: the King's B rich  
179 medium and the Hrp-inducing medium which mimics the plant apoplast (27). Results of  
180 this experiment revealed a repression of both genes in the Hrp-inducing medium  
181 compared to King's B (Figure S1), which suggests that the environment of the plant  
182 might repress *toll* and *tolR* transcription. It was therefore concluded that the Toll/R  
183 system was functional however it was repressed and/or not activated in ET under  
184 laboratory and *in planta* conditions that we have used. It cannot also be excluded that this  
185 AHL QS system is functional at very low AHL concentrations.

#### 186 **Identification of the PSV NCPPB 3335 quorum sensing regulon**

187 It was of interest to establish the loci regulated by the PssI/R system thus a whole-  
188 genome transcriptional RNAseq comparative analysis of wild type PSV NCPPB 3335  
189 and its derivative *pssI* mutant was performed. RNA was extracted from these strains  
190 grown in biological triplicates in LB broth to late-log phase and then sequenced as  
191 described in Material and Methods section. The results yielded a surprisingly small  
192 number of differentially expressed genes (DEGs) between the two strains (Table 5). To  
193 evaluate the reliability of the RNAseq results, the expression of these genes was analysed  
194 by RT-qPCR. Significant upregulation in the  $\Delta pssI$  mutant was found only for three  
195 genes which encoded for PssR (PSA3335\_1621), a pyruvate dehydrogenase E1  
196 component beta subunit (PSA3335\_1622, *pdhT*) and a pyruvate dehydrogenase E1  
197 component (PSA3335\_1624, *pdhQ*) (Table 5). On the other hand, downregulation of any  
198 of the genes identified by RNAseq analysis was not observed by RT-qPCR (Table 5). In  
199 conclusion, after combination of the results obtained by RNAseq and RT-qPCR, the *pssI*  
200 regulon of PSV NCPPB 3335 was restricted to only three genes (*pssR*, *pdhT* and *pdhQ*)

201 under the conditions tested. The *pdhT* and *pdhQ* genes were also reported to be under the  
202 control of the *pssR* homolog in *P. syringae* pv. *syringae* (PSS) strain B728a (28).  
203 Interestingly, in PSS, a regulon study also resulted in very small number of genes  
204 regulated by AHL QS which are the same loci also determined to be regulated in PSV in  
205 this study (28).

#### 206 **Identification of the ET DAPP-PG 735 quorum sensing regulon**

207 It was also of interest to determine the AHL QS regulon in ET therefore transcriptional  
208 profiling was also performed via RNAseq comparing the wild type against the ETETOI  
209 mutant as described in the Materials and Methods section. DEGs of significance ( $p \leq$   
210 0.05) were selected and listed in Table S2. In total, 308 DEGs were identified in the AHL  
211 synthase mutant ETETOI mutant, among which 162 loci were down-regulated and 146  
212 up-regulated.

213 Interestingly, 19% of DEGs (59 genes) were classified as carbohydrate metabolism  
214 (Table 6) and, among them, 18 loci of inositol catabolism, which were negatively  
215 regulated by EtoI/R. On the other hand, DEGs involved in D-galactarate, D-glucarate and  
216 D-glycerate catabolism as well as maltose and maltodextrin utilization were positively  
217 regulated by the EtoI/R system. Besides carbohydrate metabolism, EtoI/R regulated  
218 genes mostly involved in the metabolism of amino acids, loci involved in membrane  
219 transport and in respiration. Furthermore, it was established that menaquinone and  
220 phyloquinone biosynthesis, glycerolipid and glycerophospholipid metabolism were  
221 influenced by EtoI/R. In addition, 9 transcriptional regulators belonging to the DeoR,  
222 IclR, LacI and TetR families were regulated by EtoI/R QS system.

223 In order to corroborate RNAseq results, nine QS-regulated genes were randomly selected  
224 and RT-qPCR was carried out with gene-specific primers (Table 3). RNA samples  
225 extracted from three biological replicate sets were used as templates for RT-qPCR.  
226 Expression patterns determined from RT-qPCR were in good accordance with the  
227 expression levels obtained by RNAseq (Figure 3).

#### 228 **Role of PssI/R of PSV NCPPB 3335 in planta**

229 In order to determine the role of the AHL QS system of PSV NCPPB 335 in virulence,  
230 the  $\Delta pssI$  and  $\Delta pssR$  mutants and their respective complemented strains were inoculated  
231 in micropropagated and in woody olive plants. In our conditions, no significant  
232 differences in knot development among the strains tested were found either in non-woody  
233 (micropropagated) or woody olive plants (Figure 3). Additionally, all bacteria reached a  
234 similar final population within the knots. It was concluded that PSV NCPPB 3335 AHL  
235 QS did not play a significant role in virulence under the conditions tested.

#### 236 **In planta role of QS regulated loci of ET**

237 In order to study the possible role of some ET AHL QS regulated loci in the cooperative  
238 interaction with PSV, knock-out mutants in *iolD*, *iotS*, *garL*, *malk*, *gldA* and *hslV* genes  
239 were generated by insertion mutagenesis and co-inoculated with PSV in olive plants.  
240 Four of these DEGs (*iolD*, *iotS*, *garL* and *malk*) are involved in carbohydrate metabolism,  
241 which is the most representative category regulated by AHL QS in ET (see above). The  
242 *gldA* and *hslV*, on the other hand, encode for a glycerol dehydrogenase and ATP-  
243 dependent protease.

244 As previously established, co-inoculation of PSV with ET significantly increased the size  
245 of the olive knot (15, 16). When ET mutants, ETIOTS, ETMALK, ETGLDA and

246 ETHSLV were co-inoculated with PSV, olive knot size did not show any significant size  
247 alteration when compared when co-inoculated with ET wildtype (Figure 4A). Co-  
248 inoculation of PSV with ETGARL and ETIOLD, on the other hand, had a significant  
249 effect on the olive knot size with approximately a 50% reduction for ETGARL and  
250 approximately 20% increase for ETIOLD (Figure 4A). When co-inoculated with  
251 ETGARL, the colony forming units (CFU) of PSV in the knot were significantly reduced  
252 and resulted in 20% the amount of cells when co-inoculation was performed with the  
253 wildtype ET (Figure 4B). A significant reduction in the CFUs of PSV was also observed  
254 when co-inoculated with ETIOTS, ETGLDA and ETHSLV regardless that olive-knot  
255 size was not significantly affected. In order to further determine the putative role of GarL  
256 in PSV-ET interaction, we co-inoculated GFP-labeled PSV with ET wild type or the *garL*  
257 mutant constitutively expressing RFP. At 30 dpi knots were visualized in a stereoscopic  
258 microscope using GFP and RFP filters (Figure 5A, 5B) and pictures were taken and  
259 processed as described in Materials and Methods. Results show that the percentage of  
260 PSV population co-localization with ET wild type is under 5%, whereas over 75% of ET  
261 co-localize with PSV (Figure 5C). On the other hand, mutation in the ET *garL* gene  
262 resulted in a drastic reduction of ET association with PSV, with only 6.6% of the total ET  
263 population overlapping PSV. This result, together with the reduced knot size in PSV-  
264 ETGARL co-inoculation, indicated that GarL plays a major role in PSV-ET interaction.

265 **DISCUSSION**

266 There is a growing need to study interspecies bacterial interactions since it is now  
267 becoming evident that most bacteria in the wild live as part of complex communities.  
268 Moreover in relation to diseases, reports are beginning to demonstrate that pathogens  
269 undergo interactions and communicate with non-pathogenic commensal/resident host  
270 microbial flora (11, 29). We have previously reported that the olive knot disease is a  
271 model to study interspecies communication and cooperation between a bacterial pathogen  
272 and commensal bacteria in a plant disease (14, 15). This cross-communication occurs via  
273 cross-feeding/sharing of AHL QS signals whereas the mechanism(s) of cooperation  
274 leading to a more aggressive disease is currently not understood and could be due to  
275 metabolite(s) sharing and/or metabolic complementarity. In this study, we determined the  
276 QS regulons of PSV and ET in order to begin to shed some light in this cooperative  
277 interspecies interaction in a plant disease.

278 Results presented here reveal that all *P. savastanoi* isolates infecting woody plants  
279 sequenced so far, harbor an identical content of AHL QS-related genes which consist of  
280 an archetypical AHL QS pair designated as *pssI/pssR*, and two *luxR* solos. The PssI/R  
281 system was firstly reported in strain DAPP-PG 722 (15) and displays 100% identity with  
282 PssI/R of strain NCPPB 3335 (studied here). At transcriptional level there is no QS  
283 positive feedback loop regulating the AHL synthase gene in PSV NCPPB 3335 (Figure  
284 2A), which is contrast with what occurs in *P. syringae* pv *syringae* (PSS) B728a [50], a  
285 strain closely related with PSV from a phylogenetic point of view. It cannot be excluded  
286 that one of the two LuxR solos present in PSV genomes might be involved in *pssI*  
287 regulation. Moreover, AefR (AHL epiphytic fitness Regulator) positively regulates the

288 *pssI* homolog *ahII*, in *P. syringae* pv *phaseolicola* NPS3121 (30) and PSS B728a (31); a  
289 homolog of AefR is present in PSV genomes and could therefore have a similar function  
290 in regulating *pssI* in PSV.

291 *In planta* infection studies revealed that in PSV NCPPB 3335 neither *pssI* nor *pssR* are  
292 involved in virulence in the olive plant. It cannot be excluded however that AHL QS in  
293 PSV might plays a role in the epiphytic fitness/lifestyle *in planta*; QS has been shown to  
294 play a role in epiphytic fitness in PSS as well as other plant-associated bacteria (28, 31-  
295 33).

296 We found that wild type PSV NCPPB 3335 produces exclusively C6-AHL, whereas PSV  
297 DAPP-PG 722 synthesizes 3-oxo-C6- and 3-oxo-C8-AHLs (15) regardless that the *luxI*  
298 homologs are 100% identical; some other factor(s) might be responsible for the  
299 generation of different signal molecules. Overexpression of *pssI* in PSV NCPPB 3335  
300 yielded 3-oxo-C6- and 3-oxo-C8-HSLs in addition to C6-AHL (Table 2), suggesting that  
301 different expression levels between these two strains might explain differences in AHL  
302 production. AHLs are synthesized by LuxI using *S*-adenosylmethionine and an acyl  
303 group which is provided by an acyl-carrier protein (ACP) (34). We have identified an  
304 ACP-encoding gene in the genome of PSV DAPP-PG 722 (locus tag GS14\_RS0122650)  
305 which is not present in the PSV NCBBP 3335 genome; this locus might be involved in  
306 AHL synthesis and consequently lead to a dissimilar AHL profile synthesis between  
307 these two PSV strains. We previously reported 3-oxo-C6- and 3-oxo-C8-AHL production  
308 by ET DAPP-PG 735 (15) and here we demonstrated the production of four additional  
309 types of AHL (C6-, C8-, 3-oxo-C10- and 3-OH-C6-AHLs) using a more sensitive  
310 technique. The ability to produce more AHL types by ET increases its ability to cross-

311 talk with bacterial neighbours. The PSV NCPPB 3335 can synthesize three out of the six  
312 types of AHL produced by ET indicating possible eavesdropping between PSV and ET  
313 via these AHLs. This is in line with our previous study which demonstrated rescue of the  
314 PSV QS response of a *pssI* mutant by co-inoculation with ET wild type (15).

315 This study reports the genetic loci regulated by AHL QS in a woody host pathogen of the  
316 *P. syringae* complex. Previous reports involve the two *P. syringae* herbaceous pathogens  
317 *P. syringae* pv *syringae* (PSS) and *P. syringae* pv. *tabaci* (PST). PSV NCPPB 3335  
318 AHL QS regulon consists of only three genetically close loci, namely *pdhT*, *pdhQ* and  
319 *pssR*. In PSS strain B728a AHL QS regulates the transcription of only a 9 gene cluster  
320 located adjacent to the *ahlR-ahlI* locus which also contains the *pdhT* and *pdhQ* loci (28),  
321 whereas in PST strain 11528 over 300 genes were found to be regulated by QS,  
322 including *phdT*, *pdhQ* and the *pssR* homologs (35). Despite such a difference in AHL QS  
323 regulons among these strains, the transcription of *pdhT*, *pdhQ* and *pssR* (*ahlR*) is  
324 common in all *P. syringae* species and their role in *P. syringae* deserves further attention.  
325 (36).

326 QS in *Erwinia* species plays important roles in virulence determinants and secondary  
327 metabolite production (37). *E. toletana* is a harmless epiphyte and endophyte and was  
328 first isolated from olive knots caused by PSV, and is now a model to study multispecies  
329 interactions with PSV (14). ET DAPP-PG 735 possesses two canonical AHL QS systems,  
330 designated as EtoI/R and TolI/R. Prior to the availability of the genome sequence, AHL  
331 QS signals produced by ET were initially only attributed to EtoI (15). Here we report that  
332 promoter activities of *tollR* in ET, ETTOLI and ETETOI were very low and were barely  
333 detectable *in planta* and were found to be repressed by the plant apoplast mimic medium,

334 suggesting that *tollR* is stringently regulated and might need a yet unidentified stimulus  
335 to be expressed. It is common that two or more AHL QS systems coexist in one  
336 bacterium and many of these are interconnected in their regulation (38-43). The  
337 uniqueness in *E. toletana* is that one system is stringently regulated probably requiring, in  
338 addition to cell-density, an environmental stimulus in order to be activated and/or de-  
339 repressed.

340 In ET, 308 genes were found to be regulated by EtoI/R controlling diverse functions such  
341 as membrane transport, protein metabolism, respiration, stress response, cell division and  
342 cell cycle. Interestingly, 59 loci were involved in metabolism of carbohydrates including  
343 inositol, D-galactarate, D-glucarate, maltose and maltodextrin indicating that it plays an  
344 important role in carbon resource acquisition. It was therefore of interest to study whether  
345 any of these carbohydrate metabolic pathways play a role in interspecies interactions and  
346 cooperation with PSV. As shown in Figure 4, when co-inoculated with several ET  
347 mutants in these pathways, PSV reached lower population densities, indicating that *iotS*,  
348 *garL*, *gldA* and *gslV* ET genes play a role in PSV-ET cross-communication. IN addition,  
349 co-inoculation of the ET *garL* mutant with PSV resulted in a significantly smaller olive  
350 knot. The alpha-dehydro-beta-deoxy-D-glucarate aldolase GarL catalyzes the cleavage of  
351 both 5-keto-4-deoxy-D-glucarate and 2-keto-3-deoxy-D-glucarate to pyruvate and  
352 tartronic semialdehyde (44). GarL is involved in D-galactarate, D-glucarate and D-  
353 glycerate catabolism synthesizing D-glycerate from galactarate. This demonstrates that  
354 ET-PSV cross-communication also occurs through some reactions of primary metabolism  
355 that not only affect the growth of PSV *in planta*, but also its virulence.

356 In summary, this work further demonstrated the role of AHL QS in the olive knot as well  
357 as metabolic interaction. This therefore further highlights the olive knot as a good model  
358 to study bacterial interspecies interactions in planta of a plant disease.  
359

360 **MATERIALS AND METHODS**

361 **Bacterial strains, media, growth conditions and recombinant DNA techniques**

362 Bacterial strains used in this study are listed in Table 1. PSV and ET were grown at 28 °C  
363 and *Escherichia coli* was grown at 37 °C in Luria-Bertani (LB) medium (45) and Super  
364 Optimal Broth (SOB) (46). Solid and liquid media were amended when required with the  
365 appropriate antibiotic. Antibiotic concentration used were: kanamycin (Km) 10 µg ml<sup>-1</sup>  
366 for PSV and 50 µg ml<sup>-1</sup> for *E. coli*, gentamycin (Gm) 10 µg ml<sup>-1</sup>, ampicillin (Ap) 400 µg  
367 ml<sup>-1</sup> for PSV and 100 µg ml<sup>-1</sup> for *E. coli*; and tetracycline 10 µg ml<sup>-1</sup>.

368 All recombinant DNA techniques including restriction digestion, and agarose gel  
369 electrophoresis, purification of DNA fragments and ligations with T4 DNA ligase were  
370 performed as previously described (47). Plasmids were purified by using EuroGold  
371 columns (EuroClone, Italy) and were sequenced by MacroGen Europe (Amsterdam, NL)  
372 when necessary.

373 **Construction of bacterial strains**

374 Plasmids and oligonucleotides used in this study are listed in Tables 2 and 3, respectively.  
375 PSV NCPPB 3335 *pssI* (PSA3335\_1620) and *pssR* (PSA3335\_1621) mutants were  
376 generated by allelic interchange. DNA fragments of approximately 1 kb corresponding to  
377 the upstream and downstream flanking regions of the gene to be deleted were amplified  
378 in three rounds of polymerase chain reaction (PCR) using Expand High Fidelity  
379 polymerase (Roche Applied Science, Mannheim, Germany). Restriction sites for *HindIII*  
380 were included in the primers as previously described (48). The resulting products,  
381 consisting on upstream and downstream flanking regions separated by the *HindIII*  
382 restriction site, were cloned into pGEMT-Easy (Promega, Madison, WI, U.S.A.) and

383 sequenced to discard mutations. Next, the kanamycin resistance gene *nptII* was extracted  
384 by enzyme restriction from pGEMT-KmFRT- *HindIII* (49) and cloned in the plasmids  
385 mentioned above to generate pECP10-Km and pECP11-Km (Table 2). All the plasmids  
386 generated for the construction of PSV NCPPB 3335 mutants were suicide vectors in PSV.  
387 Plasmids were transferred to NCPPB 3335 by electroporation (17) and transformants  
388 were selected in LB-Km plates. To select the allelic interchange (double recombination  
389 event) and discard plasmid integration (single recombination event), individual colonies  
390 were replicated into LB-Ap plates and Ap<sup>R</sup> colonies were discarded. Southern blot  
391 analyses were carried out to confirm single integration in the correct position in PSV  
392 genome.

393 Mutation of selected genes in ET was performed via a single homologous recombination  
394 event with the use of pKNOCK-Km suicide delivery system as previously described (50)  
395 generating mutants of ETIOLD, ETIOTS, ETGARL, ETMALK, ETGLDA, ETHSLV,  
396 ETTOLI and ETTOLR. Briefly, internal fragments from *iolD* (G200\_RS0103425), *iotS*  
397 (G200\_RS0119945), *garL* (G200\_RS0124305), *malK* (G200\_RS0114460), *gldA*  
398 (G200\_RS0114990), *hslV* (G200\_RS0113655), *toll* (G200\_RS0118785) and *tolR*  
399 (G200\_RS0118780) of ET were amplified using the primers listed in Table 3 and cloned  
400 in conjugative suicide vector pKNOCK-Km. The generated plasmids having internal  
401 fragments from selected genes were transformed into *E. coli* S17-1  $\lambda$ pir and delivered to  
402 ET for its homologous recombination. Km<sup>R</sup> colonies were verified by PCR analysis  
403 followed by sequencing of the targeted gene to confirm the generation of ET mutants.

#### 404 **AHL extraction and characterization**

405 Bacterial strains were grown overnight in LB broth (final volume 100 ml); cells were  
406 then removed by centrifugation and the supernatant was used to purify AHLs. Spent  
407 supernatants were filtered (pore diameter 0.45  $\mu\text{m}$ ), mixed with one volume of 0.1%  
408 acetic acid (v/v) in ethyl acetate and incubated under shaking conditions for 30 minutes.  
409 The organic phases were dried at room temperature. The AHLs produced by each strain  
410 were identified from the organic extracts of spent supernatants by liquid chromatography-  
411 electrospray ionization-tandem mass spectrometry (LC-ESI-MS/MS) as we described  
412 previously (51). As an example of this analysis, the ion chromatograms of an AHL  
413 standard and the *E. toletana* wild type sample is provided in Figure S3.

#### 414 **Construction of plasmids and reporter assays**

415 For the complementation of PSV  $\Delta pssI$  and  $\Delta pssR$  mutant strains, the entire open reading  
416 frames of each gene and their corresponding promoter and transcriptional terminator  
417 regions were amplified by PCR using Expand High Fidelity polymerase (Roche Applied  
418 Science, Mannheim, Germany) and cloned into pGEMT-Easy (Promega, Madison, WI,  
419 USA). After sequencing to discard mutations, the fragments were directionally subcloned  
420 into pBBR:MCS5 yielding pBBR:*pssI* and pBBR:*pssR*.

421 DNA fragments of 338 and 352 bp containing *pssI* and *pssR* promoter regions,  
422 respectively, were amplified by PCR using oligonucleotides listed in Table 3 and cloned  
423 into pMP220 (52). The resulting plasmid *lacZ* transcriptional fusions were transferred to  
424 PSV by electroporation and  $\beta$ -galactosidase activity was measured as described  
425 previously (45). Bacteria were grown in LB broth amended with 10  $\mu\text{g ml}^{-1}$  tetracycline  
426 at an initial  $\text{OD}_{600\text{nm}}$  of 0.3 and  $\beta$ -galactosidase activity was measured throughout the  
427 growth curve.

428 Promoter regions of *etoI*, *etoR*, *toll* and *tolR* ET genes were amplified by PCR using the  
429 oligonucleotides listed in Table 3 and cloned in the vector pBBR:GFP (53) in order to be  
430 transcriptionally fused to a promoterless *gfp* gene. The resulting plasmids were  
431 transformed by electroporation into ET strains (54) and gene promoter activity was  
432 determined as the amount of GFP fluorescence measured in the late log phase at 510nm  
433 on a microplate reader (Perkin Elmer EnVision 2104). The expression of *toll* and *tolR*  
434 was also analyzed by RT-qPCR in King's B and Hrp-inducing medium as reported  
435 previously (48). The *etoI* and *toll* promoter activities were measured *in vivo* in mixed  
436 PSV-ET infections. Ten plants were inoculated with each of the three combinations: PSV  
437 and ET expressing a promoterless GFP (negative control), PSV and ET-pBBR:P<sub>*etoI*</sub>-GFP,  
438 and PSV and ET-pBBR:P<sub>*toll*</sub>-GFP. The presence/absence of fluorescence was verified  
439 using a stereoscopic microscope (Leica MZ FLIII; Leica Microsystems, Wetzlar,  
440 Germany).

#### 441 **RNA extraction, RNAseq and analysis**

442 Ribopure bacteria RNA isolation kit (Ambion Inc., Austin, TX, U.S.A.) was used for  
443 total RNA extraction from three biological replications. Bacteria were grown in LB until  
444 the onset of stationary phase and about  $2 \times 10^9$  cells were collected for RNA extraction  
445 following the manufacturer's instructions. Library preparation and transcriptome  
446 sequencing were performed by IGA Technology Services Srl (Udine, Italy). Briefly,  
447 libraries were constructed with TruSeq Stranded mRNA Sample Prep kit (Illumina, San  
448 Diego, CA) and single-end sequencing was carried out on HiSeq2500 (Illumina, San  
449 Diego, CA). Illumina adapters, lower quality bases and poly-A tails were removed using  
450 ERNE (55). Software and tools for *de novo* assembly and comparisons were performed as

451 previously described (56-58). The false discovery rate (FDR) with a significance level of  
452  $\leq 0.05$  and with a minimum fold change set as the threshold were used to judge the  
453 significance of gene expression difference. Reads obtained from adapter removal were  
454 aligned against GCA\_000336255.1 and GCA\_000164015.2 reference genome assemblies.  
455 Features counts produced by RNA-seq were normalized and analyzed with DeSeq2  
456 software (<http://dx.doi.org/10.1186/s13059-014-0550-8>) to calculate differential  
457 expression values ( $\log_2$  of the fold change LFC) and raw p-values. To select differentially  
458 expressed genes, genes raw p-values were corrected for multiple testing using with the  
459 false discovery rate (FDR) method (59). Final selection was based on genes with FDR  
460  $\leq 0.05$ . The original RNAseq data has been submitted in the Sequence Read Archive  
461 (SRA) as submission number SUB3743389

#### 462 **Validation of RNAseq data using qRT-PCR**

463 Quantitative real-time PCR was performed on CFX96 Touch qPCR system (Bio-Rad,  
464 Hercules, CA, USA) to validate expression patterns from transcriptome analysis. cDNA  
465 was generated following the manufacturer's protocol of Reverse Transcription system kit  
466 (Promega, Madison, WI, USA) starting with 1-2  $\mu\text{g}$  of purified RNA as input. Diluted  
467 with RNase-free water, the synthesized cDNA samples were adjusted to  $25 \text{ ng} \cdot \mu\text{L}^{-1}$  and  
468 were measured by Nano Drop 2000 (Thermo scientific, Wilmington, DA, USA). In each  
469 reaction,  $2 \mu\text{L}$  of cDNA template was mixed with GoTaq qPCR Master Mix kit (Promega,  
470 Madison, WI, USA) and specific primers (Table 3) to a final volume of  $12 \mu\text{l}$ . qPCR  
471 primer designing was performed with free online software following the instructions of  
472 Brenda Thornton and Chandak Basu (60). Each reaction was carried out initially with 2  
473 min at  $95 \text{ }^\circ\text{C}$ , followed by 45 cycles of PCR ( $95 \text{ }^\circ\text{C}$ , 15 s;  $60 \text{ }^\circ\text{C}$ , 30 s). The relative

474 transcript abundance was calculated using the cycle threshold ( $\Delta\Delta C_t$ ) method (61).  
475 Transcriptional data were normalized to the *gyrA* (for PSV) or *recA* (for ET)  
476 housekeeping genes.

#### 477 *In planta* experiments

478 Olive plants were micropropagated and inoculated as detailed previously (62). Briefly,  
479 micropropagated olive plants were wounded by excision of an intermediate leaf and  
480 infected in the stem wound with a bacterial suspension under sterile conditions. For this  
481 purpose, bacterial lawns were grown for 48h on LB plates, washed twice with 10 mM  
482  $MgCl_2$  and resuspended in 10 mM  $MgCl_2$  to an approximate concentration of  $10^8$   
483 CFU·mL<sup>-1</sup>. Suspension of PSV alone or mixed with ETIOLD, ETIOTS, ETGARL,  
484 ETMALK, ETGLDA and ETHSLV respectively in 1:1 (vol:vol) ratio were prepared.  
485 Plants were inoculated with approximately  $5 \times 10^3$  total CFU and kept in a growth chamber  
486 for 30 days, as previously described (62). The morphology of the knots was observed  
487 with a stereoscopic microscope 30 days post-inoculation (dpi) (Leica MZ FLIII; Leica  
488 Microsystems, Wetzlar, Germany), also equipped with a 100 W mercury lamp, a GFP2  
489 filter (excitation 480/40 nm; emission 510LP nm) and a red fluorescent protein (RFP)  
490 filter (excitation 546/10 nm; emission 570LP nm). For the quantification of green (GFP-  
491 tagged PSV) and red (RFP-tagged ET and ETGARL strains) pixels, two pictures per knot  
492 (corresponding to the front and back sides of the tumour) were taken with each the GFP2  
493 and RFP filters. Pictures were transformed to 8-bits images and overlapped with Fiji  
494 ImageJ (<https://imagej.net/Fiji>) using the Image correlator plugin. The number of green  
495 pixels overlapping red pixels, indicating the population of PSV that co-localize with  
496 ET/ETGARL, was determined for both the front and the back sides of each knot and an

497 average per knot was calculated. An identical procedure was used to determine the  
498 percentage of ET or ETGARL population that co-localize with PSV. Bacteria were  
499 recovered from the knots using a mortar and pestle containing sterile  $MgCl_2$  10 mM.  
500 Serial dilutions were plated on LB plates supplemented with the corresponding antibiotic  
501 when required. Knots were 3D scanned and the knot size determined using the Neftabb  
502 Basic 5.2 software.

503 The virulence of PSV and its derived mutants and complemented strains was also  
504 analysed on 1-year old olive plants on 1-year old olive plants (*Olea europaea*) derived  
505 from a seed originally collected from a cv. Arbequina plant as detailed before (17, 63, 64).  
506 Morphological changes scored at 90 dpi were captured with a high-resolution camera  
507 Canon D6200 (Canon Corporation, Tokyo, Japan). The knot volume was calculated from  
508 a minimum of three representative knots as described previously (15, 65).

509

#### 510 **Acknowledgements**

517 NCPPB 3335 and ET DAPP-PG 735. (A) *pssI* and *pssR* represent a canonical *luxI/luxR*  
518 gene pair, whereas *luxR2* and *luxR3* correspond to orphan *luxR* homologs in PSV NCPPB  
519 3335. (B) *etoI/etoR* and *toll/tolR* represent two canonical *luxI/luxR* gene pairs of ET  
520 DAPP-PG 735. Codes above arrows correspond to locus tags

521 **Figure 2.** Promoter activities of PSV and ET quorum sensing genes. (A)  $\beta$ -galactosidase  
522 activity of *pssI* promoter fusion to *lacZ* measured in PSV NCPPB 3335,  $\Delta$ *pssI* and  $\Delta$ *pssR*  
523 at log (4 hours incubation) and stationary phase (10 hours incubation). PSV harboring a  
524 promoterless *lacZ* (empty pMP220 plasmid) was included as a control. Asterisks indicate  
525 a significant difference (student's *t* test,  $P < 0.05$ ) in promoter activity in stationary phase  
526 compared to log phase (B) GFP fluorescence of *etoI*, *etoR* *toll* and *tolR* fusions to *gfp*  
527 measured in ET, ETTOLI and ETETOI backgrounds. GFP fluorescence was normalized  
528 to OD<sub>600</sub>. Bars represent the average of three independent replications  $\pm$  the standard  
529 deviation

530 **Figure 3.** Evaluation of RNAseq-based expression patterns of ET using RT-qPCR. The  
531 expression patterns of randomly selected genes were analyzed by RT-qPCR to validate  
532 RNAseq results. The values of fold difference were average of three biological replicates  
533 which were calculated by using comparative quantification method. Log<sub>2</sub> ratio of  
534 obtained values was compared with log<sub>2</sub> ratio of (ETETOI/ET) FPKM values.

535 **Figure 4.** Role of ET AHL QS loci in the PSV-ET cooperation *in planta*. (A) Size of the  
536 knots induced in micropropagated olive plants at 30 dpi by PSV in combination with ET

537 strains. (B) CFU of PSV and (C) CFU of ET recovered from knots. Bars indicate the  
538 average of, at least, three knots  $\pm$  standard deviation.

539 **Figure 5.** Knots developed at 30 dpi in micropropagated olive plants after co-inoculation  
540 of GFP-labelled PSV with RFP-labelled ET or ETGARL. (A) Co-inoculation using GFP-  
541 labelled PSV and RFP-labelled ET. (B) Co-inoculation using GFP-labelled PSV and  
542 RFP-labelled ETGARL. (C) Percentage of the PSV and ET/ETGARL populations co-  
543 localization within the knot. Bars represent the average of six independent knots  $\pm$   
544 standard deviation.

578

579

<sup>a</sup>Upregulated or downregulated genes in the  $\Delta pssI$  mutant according to RNAseq data.

<sup>b</sup>UN, unnamed

<sup>c</sup>The  $\log_2$  (fold change) obtained in the RNAseq and RT-qPCR experiments are represented. The fold change refers to the ratio of the average expression obtained in the  $\Delta pssI$  mutant versus the wild type strain in three biological replicates. Genes which QS-dependent expression was corroborated by RT-qPCR are underlined

580 **Table 6.** Genes regulated by *etoI* in ET DAPP-PG 735 classified as carbohydrates  
 581 metabolism
