Abstract

We recently demonstrated that SB269652 (**1**) engages one protomer of a dopamine D₂ receptor (D₂R) dimer in a bitopic mode to allosterically inhibit the binding of dopamine at the other protomer. Herein, we investigate structural determinants for allostery, focusing on modifications to three moieties within **1**. We find that orthosteric ‘head’ groups with small 7-substituents were important to maintain the limited negative cooperativity of analogues of **1**, and replacement of the tetrahydroisoquinoline head group with other D₂R ‘privileged structures’ generated orthosteric antagonists. Additionally, replacement of the cyclohexylene linker with polymethylene chains conferred linker length dependency in allosteric pharmacology. We validated the importance of the indolic NH as a hydrogen-bond donor moiety for maintaining allostery. Replacement of the indole ring with azaindole conferred a 30-fold increase in affinity whilst maintaining negative cooperativity. Combined, these results provide novel SAR insight for bitopic ligands that act as negative allosteric modulators of the D₂R.

Introduction

The dopamine D₂ receptor (D₂R), a class A G protein-coupled receptor (GPCR), is a therapeutic target for central nervous system disorders including schizophrenia and Parkinson's disease.¹ To date, drug discovery at this target has focused on the orthosteric binding site, with clinically marketed antipsychotics being either antagonists/inverse agonists or partial agonists at the D₂R.² Unfortunately, such approaches are associated with significant side effects; in particular, high occupancy orthosteric blockade of the D₂R provided by first generation antipsychotics, while effective in treating the positive symptoms of the disease, is associated with extrapyramidal side effects.²

It has become apparent that many class A GPCRs have at least one other topographically distinct, allosteric binding site that can be targeted by small molecules.³⁻⁶ Ligands that behave as allosteric modulators may offer advantages over purely orthosteric ligands, including increased receptor subtype selectivity and maintenance of spatiotemporal patterns associated with the signals of the endogenous ligand.⁷ These features make negative allosteric modulators an attractive prospect for the treatment of schizophrenia, where partial blockade by a negative allosteric modulator with limited negative cooperativity, may represent a safer therapeutic option for the positive symptoms of schizophrenia.⁸ More recently, concomitantly targeting both orthosteric and allosteric sites with bitopic ligands, in which allosteric and orthosteric pharmacophores have been linked together, has been explored as a means of developing more selective GPCR ligands.⁹⁻¹¹

SB269652 (**1**)^{12,13} was recently described as the first small molecule negative allosteric modulator of the D₂R.¹³ This was somewhat surprising, given that **1** contains structural features of numerous orthosteric D₂-like receptor ligands.^{12,14-16} Indeed, the 1,2,3,4-tetrahydroisoquinoline (THIQ) 'head' group of **1** contains a basic tertiary amine that is expected to form a salt bridge with the conserved aspartate (Asp^{3.32}, Ballosteros-Weinstein

1
2
3 nomenclature¹⁷) of aminergic GPCRs, and would thus compete with the binding of dopamine.
4
5 The lipophilic 1*H*-indole-2-carboxamide ‘tail’ group is characteristic of the lipophilic
6
7 appendages that are a feature of numerous subtype selective D₂-like receptor ligands.¹⁴ Such
8
9 appendages have been proposed to extend into a secondary pocket away from the orthosteric
10
11 pocket.^{14,18,19}
12
13

14 We have recently confirmed that **1** displays limited negative allosteric cooperativity at the
15
16 D₂R with a sub-micromolar binding affinity, but found that truncated derivatives of **1**
17
18 containing a THIQ moiety act in a competitive manner with dopamine.²⁰ We demonstrated
19
20 that **1** acts via a novel mechanism, engaging one protomer of a D₂R dimer in a dual
21
22 orthosteric/allosteric (or bitopic) mode, to negatively modulate dopamine binding and
23
24 function at the other protomer (**Figure 1**).²⁰ This mechanism allowed us to reconcile an
25
26 orthosteric mode of interaction with the allosteric pharmacology of SB26965. Furthermore,
27
28 the interaction of the 1*H*-indole-2-carboxamide moiety of **1** with a secondary, or allosteric,
29
30 pocket between the extracellular face of transmembrane domains (TMs) 2 and 7, was shown
31
32 to be a requirement for the allosteric pharmacology of **1**. These findings presented a novel
33
34 mode of action for small molecules at this therapeutically important target.²¹ Additionally, we
35
36 were able to use **1** as a probe to identify D₂R dimers in rat striatal tissue, adding to previous
37
38 evidence that this receptor can function as a dimer or oligomer.²²⁻²⁶ It should be noted that the
39
40 above mechanism differs from previous studies that attempted to target D₂R
41
42 dimers/oligomers using bivalent ligands that simultaneously occupy binding sites on two
43
44 adjacent receptors.^{27,28}

Currently, there is limited SAR data associated with **1**, indicating scope for further structural interrogation (**Figure 2**). We therefore undertook a study to identify novel negative allosteric modulators for the D₂R, based on the structure of **1**. In particular, given the similarity of **1** to other D₂-like selective ligands^{14,29} that display competitive pharmacology with dopamine, it is important to understand the key structural features of **1** that underlie its distinct allosteric pharmacology. Through modifications to the scaffold of **1**, as illustrated in **Figure 2**, we aimed to identify key molecular features that were responsible for changes in functional affinity and negative allosteric cooperativity, thereby enhancing our understanding of the nature of this bitopic mechanism and of allosterity at the D₂R.

<Insert Figure 2>

Synthesis

We generated a focused library of analogues of **1** to examine the effect on functional affinity and allosteric pharmacology of the scaffold, as depicted in **Figure 2**. These included replacement of the 7-cyano group with various substituents of differing size and electronic effects (H, F, Cl, Br and CF₃); replacement of the THIQ core with D₂R privileged motifs and related bicyclic systems (2,3,4,5-tetrahydro-1*H*-benzo[*c*]azepine, 4,5,6,7-tetrahydrothieno[3,2-*c*]pyridine, 1-(2-methoxyphenyl)piperazine (2-MPP) and 1-(2,3-dichlorophenyl)piperazine (2,3-DCPP)); and the installation of polymethylene spacers in place of the cyclohexylene linker. We also explored the role of hydrogen-bond donors in **1** by examining the effect of alkylation of both the indolic and carboxamide NH moieties, and by investigating the influence of various heteroatoms on the tail group. In addition, we sought to evaluate the impact of replacing the indole moiety with monocyclic (e.g. pyrrole and

1
2
3 pyrrolidine) and various electron-rich and electron-deficient bicyclic (e.g. benzofuran and
4
5 azaindole, respectively) heterocyclic systems.
6

7
8 The synthesis of all compounds generally followed previously established methods for the
9
10 synthesis of **1**,^{12,20} and other related compounds recently reported by our research group.³⁰
11
12 For the synthesis of compounds with modifications to the THIQ core, various
13
14 tetrahydroisoquinolines, phenylpiperazines, or tetrahydrothienopyridine, were commercially
15
16 sourced. The compound 2,3,4,5-tetrahydro-1*H*-benzo[*c*]azepine (**4**) was synthesized by a
17
18 Schmidt reaction of 1-tetralone (**2**) in concentrated hydrochloric acid, favouring the alkyl-
19
20 migration lactam **3** as the major product,³¹ shown in **Scheme 1**. Reduction of **3** with lithium
21
22 aluminium hydride gave **4** in good yield.
23
24

25

28
29

30
31
32 The preparation of the *trans*-cyclohexylene spacer unit, illustrated in **Scheme 2**, followed
33
34 methods that we previously reported, to afford aldehyde **8** from 4-nitrophenylacetic acid
35
36 (**5**).³⁰ The preparation of **1** from **8** was carried out using literature procedures.^{12,20} Compound
37
38 **8** was treated under reductive alkylation conditions (NaBH(OAc)₃) with the various
39
40 secondary amine head groups (**9b-j**), which were prepared as in **Scheme 1**, or commercially
41
42 supplied as the free base or hydrochloride salt. In the case where hydrochloride salts were
43
44 used, *N,N*-diisopropylethylamine (DIPEA, Hünig's base) was also added to liberate the free
45
46 base. This process afforded the corresponding tertiary amines (**10b-j**). Deprotection of the *N*-
47
48 Boc group in TFA/DCM, followed by basic workup or 4 M HCl/1,4-dioxane, afforded the
49
50 primary amines (**11a, c-h**) or the corresponding dihydrochloride (**11b**) or trihydrochloride
51
52 salts (**11i-j**), respectively. The final compounds (**12b-j**) were then prepared by treatment of
53
54 **11b-j** with 1*H*-indole-2-carboxylic acid in the presence of *O*-(6-chlorobenzotriazol-1-yl)-

11
12 We next explored compounds with modifications to the spacer group of **1**, as illustrated in
13 **Scheme 3**, using various starting points depending on commercial availability. For the
14 synthesis of the propylene spacer, 3-bromopropylamine hydrobromide (**13a**) underwent *N*-
15 Boc protection, before alkylation with 7-cyano-1,2,3,4-tetrahydroisoquinoline (7-CTHIQ, **9a**)
16 in the presence of K₂CO₃ in refluxing MeCN, in moderate yield. For the synthesis of
17 compounds with butylene, pentylene and hexylene spacers, the appropriate aminoalcohol
18 (**13b-d**) underwent *N*-Boc protection, followed by activation of the alcohol using
19 methanesulfonyl chloride, and subsequent nucleophilic substitution with **9a**. The *N*-Boc-
20 protected compounds **16a-d** underwent deprotection with TFA, prior to HCTU-mediated
21 coupling with 1*H*-indole-2-carboxylic acid to give the final products, **18a-d**.

38
39
40
41 In order to explore the requirements of the 1*H*-indole-2-carboxamide tail group for
42 allosteric pharmacology, we generated a number of analogues of **1** bearing structural
43 modifications to the tail moiety. To assess the role of the amide NH in a hydrogen-bond
44 donating interaction, we synthesised the *N*-methylated indole-2-carboxamide analogue (**23**),
45 which removes one potential hydrogen-bond donor present in **1**. For the synthesis of **23**, ethyl
46 2-(*trans*-4-((*tert*-butoxycarbonyl)amino)cyclohexyl)acetate (**7**), was *N*-methylated using an
47 excess of sodium hydride and iodomethane in DMF over 3 days (**Scheme 4**), and ester **19**
48 was isolated in moderate yield. This method was chosen in favor of Eschweiler-Clarke

3 methylation of amine **6** due to the large scale of **7** that was already synthesized, and was
4 readily accessible for further reactions. **19** was subsequently reduced using DIBAL-H to the
5 corresponding aldehyde (**20**), before reductive alkylation with **9a** in the presence of
6 NaBH(OAc)₃ to give **21**. The *N*-Boc group was then removed with TFA in DCM to give
7 secondary amine **22**, which was coupled with 1*H*-indole-2-carboxylic acid in the presence of
8 HCTU to give the desired *N*-methylated product (**23**).

20
21 To further our understanding of a hydrogen-bonding interaction between the 1*H*-indole-2-
22 carboxamide moiety of **1** and Glu95^{2,65}, as we have previously described,²⁰ we generated
23 compounds which were completely devoid of a hydrogen-bond donor group on the indole
24 moiety. To do this, we generated the benzofuran-2-carboxamide (**25a**), benzo[*d*]oxazole-2-
25 carboxamide (**25b**), 1*H*-indene-2-carboxamide (**25c**) and 1-methyl-1*H*-indole-2-carboxamide
26 (**25d**) analogues. We also investigated analogues which ‘fine-tuned’ the hydrogen-bond
27 donating ability by modifying the electronic properties of the indole moiety, namely by the
28 synthesis of the 1*H*-benzo[*d*]imidazole-2-carboxamide (**25e**) and 1*H*-pyrrolo[2,3-*b*]pyridine-
29 2-carboxamide (**25f**) analogues. The synthesis of these compounds, depicted in **Scheme 5**,
30 required coupling of the primary amine **11a** with the appropriate commercially available
31 carboxylic acid analogues (benzofuran-2-carboxylic acid (**24a**), potassium benzo[*d*]oxazole-
32 2-carboxylate (**24b**), 1*H*-indene-2-carboxylic acid (**24c**), 1-methyl-1*H*-indole-2-carboxylic
33 acid (**24d**), benzo[*d*]imidazole-2-carboxylic acid (**24e**), 1*H*-pyrrolo[2,3-*b*]pyridine-2-
34 carboxylic acid (**24f**) in the presence of HCTU and DIPEA, to furnish the desired final
35 products (**25a-f**).

28 **Results and Discussion**

29
30 All compounds were tested for their ability to bind the D₂R in a competition binding assay
31 using the antagonist [³H]raclopride. For competitive ligands, a value of affinity (K_B) was
32 derived. However, some ligands were unable to completely inhibit the binding of
33 [³H]raclopride even at saturating concentrations, consistent with an allosteric mode of
34 interaction (**Figure 3A**, **Tables 1-4**). In these cases, data were fit using an allosteric ternary
35 complex to derive a value of affinity, denoted as K_B , and cooperativity with [³H]raclopride
36 (α). However, this assay does not provide information regarding the effect of compounds
37 upon the neurotransmitter dopamine. Therefore, the activity of all compounds was tested in
38 an assay measuring phosphorylation of ERK1/2 through activation of the long isoform of the
39 D₂R (D_{2L}R) expressed in FlpIn CHO cells. This assay provides a robust, medium throughput
40 measurement of D₂R activation. Compounds were tested for their ability to antagonize the
41 action of increasing concentrations of dopamine. An example of these data is presented in
42 **Figure 3B**. These data were fit with either a derivation of the operational model of

1
2
3 allosterism³² (see supplementary information) to derive values of functional affinity (denoted
4 as K_B), and allosteric cooperativity with dopamine (denoted as $\alpha\beta$, a composite parameter
5 where α is negative cooperativity with dopamine binding, and β denotes modulation of
6 dopamine efficacy); a Gaddum-Schild model of competitive antagonism to derive values of
7 functional affinity (K_B); and, a Schild slope, where a Schild slope that is not significantly
8 different from unity (Schild slope = 1) indicates competitive antagonism. For each
9 compound, data were analysed with both models and the best fit determined by an F-test.
10 These data are reported in **Tables 1-4** and are presented as logarithms to allow statistical
11 comparison.³³ Values of $\text{Log}\alpha\beta < 0$ signify negative cooperativity with dopamine. The
12 overall correlation between the values of affinity obtained in the functional and binding
13 assays was good ($R^2 = 0.73$, Supplementary figure 1). Therefore, because we were most
14 interested in the functional effect of **1** and its analogues upon the action of dopamine, we
15 focus upon these data for structure-activity analysis. The lead compound (**1**) acted as a
16 negative allosteric modulator at the D₂R, with moderate functional affinity ($K_B = 776$ nM).
17 The limited dextral displacement of the dopamine dose-response curve by increasing
18 concentrations of **1** is characteristic of the action of a negative allosteric modulator, and the
19 value of negative cooperativity ($\text{Log}\alpha\beta = -1.23 \pm 0.14$) translates to a maximal 17-fold
20 decrease in dopamine potency (**Figure 3B, Table 1**).

43 <Insert Tables 1-4>
44

45 We first examined modifications to the 7-CTHIQ-containing head group of **1** (**Table 1**).
46 Stemp et al.¹² incorporated the 7-cyano substituent to deactivate the THIQ ring system for the
47 purposes of reducing *in vivo* metabolism, thus increasing oral bioavailability. We determined
48 that replacement of the nitrile group with hydrogen (**12b**) resulted in a significant 9-fold
49 increase in functional affinity ($K_B = 87$ nM), but no significant change to allosteric
50 cooperativity ($\text{Log}\alpha\beta = -1.04 \pm 0.14$) at the D₂R (**Table 1**). To further explore the effect of
51
52
53
54
55
56
57
58
59
60

1
2
3 atomic size and electronegativity in the 7-position, we generated a series of 7-halogeno
4 analogues of **1**. The 7-fluoro analogue (**12c**) resulted in no significant change in functional
5 affinity ($K_B = 1.05 \mu\text{M}$) compared to **1**, whilst displaying weaker negative allosteric
6 cooperativity ($\text{Log}\alpha\beta = -0.69 \pm 0.10$). A chloro substituent at the 7-position (**12d**) had a
7 similar effect to **12c**, with no significant change in functional affinity ($K_B = 2.04 \mu\text{M}$) and
8 significantly diminished negative allosteric cooperativity ($\text{Log}\alpha\beta = -0.66 \pm 0.10$, Table 1)
9 relative to **1**. While incorporation of a 7-bromo group (**12e**) resulted a significant gain in
10 functional affinity ($K_B = 138 \text{ nM}$), increasing concentrations of this compound caused a
11 limitless dextral shift of the dopamine dose-response curve that was best fit by a competitive
12 mode of interaction (**Figure 3C**) although the Schild slope was less than unity (**Table 1**).
13 Similarly, incorporation of a trifluoromethyl group at the 7-position (**12f**) resulted in a change
14 in pharmacology from allosteric to competitive antagonism but maintained a functional
15 affinity ($K_B = 891 \text{ nM}$) comparable to **1**. These modifications demonstrate that the size and
16 degree of electronegativity of the 7-substituent may be an important determinant of both
17 functional affinity and negative cooperativity. Indeed, a comparison of the van der Waals
18 (vdW) radii³⁴ of the substituent in the 7-position suggests that smaller substituents are more
19 optimal for maintaining allosteric pharmacology, whereas the inductive effect of the
20 substituent³⁵ has less relationship to functional affinity or allosteric pharmacology. The 7-
21 fluoro (**12c**) and 7-trifluoromethyl (**12f**) analogues both exhibit a similar inductive effect ($\sigma_{\text{I-F}} = 0.45$,
22 $\sigma_{\text{I-CF}_3} = 0.38$), and display similar affinity. However, the smaller fluoro substituent
23 (vdW radius 1.47 \AA) displays allosteric pharmacology whereas the larger trifluoromethyl
24 substituent (vdW radius 2.43 \AA) is a competitive antagonist. Interestingly, the 7-bromo
25 analogue (**12e**) demonstrates a significantly greater functional affinity compared to the
26 corresponding 7-trifluoromethyl (**12f**) and 7-chloro (**12d**) analogues, yet these substituents
27 have comparable vdW radii. This may result from the greater degree of halogen bonding^{36,37}

16 We next examined the effect of expanding the size of the heterocyclic ring of the THIQ
17 scaffold, without any aromatic substitution, to tetrahydrobenzo[*c*]azepine (**12g**), which
18 resulted in a 3-fold loss of functional affinity ($K_B = 2.57 \mu\text{M}$) and no significant change in
19 negative allosteric cooperativity ($\text{Log}\alpha\beta = -0.79 \pm 0.12$, **Table 2**). We also examined the
20 effect of bioisosteric replacement of the fused benzene ring for thiophene to afford the
21 tetrahydrothieno[3,2-*c*]pyridine (**12h**), which displayed no change in functional affinity ($K_B =$
22 $339 \mu\text{M}$) but significantly reduced negative allosteric cooperativity compared to **12b** ($\text{Log } \alpha\beta$
23 $= -0.51 \pm 0.10$, **Table 2**).

33

34 The strategy of ‘core hopping’ was also investigated, whereby the THIQ scaffold was
35 replaced with other core substructures, (2-methoxyphenyl)piperazine (**12i**) and (2,3-
36 dichlorophenyl)piperazine (**12j**), which are known to be privileged scaffolds for the
37 D_2R .^{28,39,40} The incorporated modification to (2-methoxyphenyl)piperazine (**12i**) resulted in
38 the compound with the highest functional affinity of the series ($K_B = 0.26 \text{ nM}$), yet displayed
39 competitive pharmacology with dopamine. Similarly, modification to the 1-(2,3-
40 dichlorophenyl)piperazine (**12j**) resulted in high functional affinity ($K_B = 1.38 \text{ nM}$), and also
41 behaved competitively (**Table 2**). However, these data were best fit by Schild slope of $0.57 \pm$
42 0.12 and a decrease in the maximal effect of dopamine was observed, both indicators of
43 hemiequilibrium conditions.

1
2
3 Together, these results suggest that subtle modifications to the head group can have
4 significant effects on both functional affinity and negative allosteric cooperativity. These
5 observations are not surprising given we, and others, have shown that subtle changes to
6 ligand-receptor interactions in the orthosteric binding site of the D₂R of ligands with similar
7 scaffolds can modulate affinity, subtype selectivity, efficacy and even biased
8 agonism.^{18,30,41,42} When the THIQ head group was replaced with 'privileged
9 scaffolds'^{28,39,40,43,44} (**12i** and **12j**), we observed a change from allosteric to competitive
10 pharmacology accompanied by an increase in affinity. This increase in affinity is reflected by
11 a comparison of the literature binding affinities of the respective head groups without
12 modification where the THIQ head group displays lower affinity (**9a**, D₂R-K_B = 2.5 μM;²⁰)
13 than either of the privileged motifs (**9i**, D₂R-K_B = 0.137 μM;¹⁸ **9j**, D₂R-K_B = 0.680 μM¹⁸).
14 Furthermore, the competitive rather than allosteric pharmacology of **12i** and **12j** is consistent
15 with a bitopic mode of engagement for **1** at the D₂R, whereby contacts within both the
16 conserved orthosteric and putative allosteric pocket are critical for its pharmacology. Indeed
17 positioning of the secondary pharmacophore within the allosteric binding site may be
18 dependent on the binding orientation of the head group within the orthosteric pocket.

35
36
37

38 The next molecular feature of **1** that we focused on was the *trans*-cyclohexylene spacer
39 group (**Table 3**). We have previously shown the importance of the spacer group in that
40 modification of stereochemistry around the 1,4-disubstituted cyclohexylene motif from *trans*
41 to *cis* can cause a switch from negative allosteric cooperativity to competitive antagonism.²⁰
42 We sought to examine the importance of spacer configuration by installing simple flexible
43 spacers with nonfunctionalized polymethylene extensions. The modification from the *trans*-
44 cyclohexylene spacer group to the 1,3-propylene spacer (**18a**) or a 1,4-butylene spacer (**18b**)
45 resulted in a significant increase in functional affinity (K_B = 138 nM and K_B = 81 nM,
46 respectively) and maintenance in the level of negative allosteric cooperativity relative to **1**
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 (Table 3). Interestingly, incorporation of the 1,5-pentylene spacer (**18c**) displayed functional
4 affinity ($K_B = 132$ nM) no different from the 1,3-propylene spacer (**18a**), yet displayed
5 competitive pharmacology with dopamine. However, allosteric pharmacology was restored
6 for the 1,6-hexylene-containing analogue (**18d**) ($\text{Log}\alpha\beta = -1.68 \pm 0.35$) and was accompanied
7 by a further significant increase in functional affinity ($K_B = 30$ nM). The use of flexible
8 linkers has also been used to explore the distance between such orthosteric and allosteric sites
9 or even between orthosteric sites within GPCR receptor dimers.^{9,11,45,46} Our findings
10 demonstrate that flexibility in the spacer region is beneficial for enhancements to functional
11 affinity relative to the rigid cyclohexylene spacer. This result could be expected given the
12 ability for ligands to occupy two binding sites simultaneously could be more energetically
13 favourable with a flexible linker.^{11,47-49} However, it should be noted that no such
14 enhancements in binding affinity were observed. Such discrepancies between binding and
15 functional affinity has been the focus of a number of recent papers.^{50,51} Indeed, we observed a
16 similar discrepancy in a series of structurally related biased agonists at the D₂R.³⁰ Of
17 particular interest, the 1,5-pentylene analogue (**18c**) displays competitive antagonism,
18 whereas analogues containing the 1,3-propylene (**18a**), 1,4-butylene (**18b**) and 1,6-hexylene
19 (**18d**) spacers display negative allosteric cooperativity. Although such linkers are flexible,
20 they possess a degree of conformational constraint such that the odd numbered carbon chain
21 of **18c** may orientate the secondary 1*H*-indole-2-carboxamide pharmacophore into an
22 unfavourable position for interaction with the allosteric binding pocket. This is plausible
23 given we have previously shown that orientation of **1** in the binding pocket requires a linear
24 orientation of the allosteric moiety relative to the head group, and that a different orientation
25 (i.e. from *trans* to *cis* orientation of the 1,4-cyclohexylene spacer) resulted in loss of allosteric
26 pharmacology.²⁰ Furthermore, previous studies on bitopic ligands have demonstrated a
27 linker-length dependency upon the novel pharmacology conferred by engagement of both

4
5 agonism.^{9,11}
6

7
8 We next examined the effect of modifying the 1*H*-indole-2-carboxamide tail group of **1**,
9
10 which we have previously shown to form important interactions with residues in a secondary
11 binding site of the D₂R,²⁰ and that these interactions are crucial for the determination of
12 negative allosteric cooperativity (**Table 4**). Specifically, we have demonstrated the role of
13 hydrogen bonding interactions between the indolic NH and Glu95^{2,65} as a determinant of
14 negative allosteric cooperativity and functional affinity. Therefore, we synthesized analogues
15 of **1** with variations to the tail group to better examine this effect. The 1-methylindole
16 analogue (**25d**) which, as previously described,²⁰ can no longer act as a hydrogen bond donor,
17 displayed improved functional affinity for the D₂R ($K_B = 72$ nM), yet behaved as a
18 competitive antagonist. Given there is another potential hydrogen bond donating nitrogen in
19 the near vicinity, we generated the *N*-methylated carboxamide analogue (**23**), which resulted
20 in improved functional affinity ($K_B = 91$ nM) as compared to **1** ($K_B = 776$ nM), and retained
21 negative allosteric cooperativity albeit reduced ($\text{Log}\alpha\beta = -0.57 \pm 0.10$). This supported our
22 hypothesis that a hydrogen bond between the indolic NH (and not the amide NH) and
23 Glu95^{2,65} is crucial for negative allosteric cooperativity.
24
25
26

28
29
30
31
32
33
34
35
36
37
38
39

40 However, because replacement of a hydrogen with a methyl group also introduces extra bulk,
41 we further investigated this hypothesis by examining other tail groups (**Table 4**) that cannot
42 act as hydrogen bond donors yet retain similar steric properties to the lead molecule, **1**. The
43 benzofuran analogue (**25a**) displayed increased functional affinity ($K_B = 18$ nM) relative to **1**,
44 yet acted as a competitive antagonist, whereas the benzoxazole (**25b**) (also incapable of
45 hydrogen bond donation) demonstrated similar functional affinity ($K_B = 18$ nM) to **25a**, and
46 was best fit by a model of competitive antagonism. However, it should be noted that in both
47 cases the Schild slope obtained in this analysis was significantly less than unity. The indene
48
49

51
52
53
54
55
56
57
58
59
60

1
2
3 analogue (**25c**), resulting in removal of all heteroatoms in the tail group, caused a significant
4
5 increase in functional affinity ($K_B = 25$ nM) relative to **1** and again behaved as a competitive
6
7 antagonist. These results support the hypothesis that maintaining the hydrogen bonding
8
9 interaction between the receptor (most likely with the Glu^{2.65} highlighted as important for the
10
11 allosteric pharmacology of **1**²⁰) and the indolic NH moiety is a determining factor for
12
13 negative allosteric pharmacology. Disturbance of this interaction has shown in all cases to
14
15 result in both competitive antagonism and a significant increase in functional affinity relative
16
17 to **1**, confirming the results of our previous study.²⁰ However, our data also suggests that this
18
19 hydrogen bonding interaction may make the interaction of the head group with the orthosteric
20
21 pocket less favourable, thus conferring a loss of affinity for such bitopic ligands.
22
23

24
25 We subsequently explored further changes to the tail group to examine the effect of
26
27 modifying the acidity of the indolic NH moiety, and also the lipophilicity and size of the tail
28
29 group. The benzimidazole analogue (**25e**) presented a tail moiety that is theoretically a
30
31 stronger hydrogen bond donor than indole (benzimidazole $pK_a = 16.4$, indole $pK_a = 21.0$)⁵²
32
33 due to the anionic stabilizing effect of the second additional electronegative nitrogen atom.
34
35 This modification displayed no significant change in functional affinity ($K_B = 174$ nM), yet
36
37 displayed pharmacology consistent with competitive antagonism of dopamine. This was a
38
39 surprising finding given the previously established importance of hydrogen-bond donating
40
41 properties on the indolic NH moiety. The 5-membered ring of the benzimidazole system is
42
43 electron-deficient compared to its electron-rich indole counterpart of **1**, and may govern the
44
45 level of negative allosterism or lack thereof when binding to the secondary binding pocket.
46
47 Similarly, the benzimidazole NH of **25e** may be in a different relative orientation compared
48
49 to the indole NH of **1** as a result of the differing alignment of intramolecular dipoles of the
50
51 respective molecules. This could potentially direct the benzimidazole NH opposite relative to
52
53 the amide NH and therefore impact on hydrogen-bond donating/accepting interactions with
54
55
56
57
58
59
60

1
2
3 Glu95^{2,65} in the allosteric binding site. Further experiments are required to elucidate precise
4
5 reasons for this finding.
6

7
8 Interestingly, the 7-azaindole analogue (**25f**) caused a significant increase in functional
9
10 affinity ($K_B = 23$ nM) but with maintenance of the allosteric pharmacology ($\text{Log}\alpha\beta = -1.39 \pm$
11
12 0.16). The chemical and physical properties of 7-azaindole are considerably different to those
13
14 of indole⁵³ and present multiple hydrogen-bonding opportunities, including H-bond donating
15
16 from two different nitrogen atoms, and multiple H-bond acceptor sites.⁵⁴ Given that **25f**
17
18 displays such high functional affinity whilst retaining allosteric pharmacology, it is
19
20 reasonable to consider that the unique physical and electronic effects of 7-azaindole allows
21
22 important hydrogen-bond donating/accepting interactions with residues in the allosteric
23
24 binding site, including Glu95^{2,65}, which promote both high affinity and allosteric
25
26 pharmacology.
27
28

29
30 We then explored the pyrrole analogue (**26**) as a ring-deleted analogue of **1** to examine the
31
32 biological effect of reducing lipophilicity whilst retaining the ability for hydrogen-bond
33
34 donation, and preserving similar acidity (pyrrole- $\text{p}K_a = 23.0$) to indole (indole- $\text{p}K_a = 21.0$).⁵²
35
36 This resulted in a significantly increased functional affinity ($K_B = 3$ nM), yet as a competitive
37
38 antagonist. This finding indicates that the more extensive planar aromatic structures in the
39
40 allosteric binding pocket may also be crucial for allosteric pharmacology, which has been
41
42 previously suggested to be important for improving selectivity of compounds for D₂-like
43
44 receptor subtypes.^{14,19} While it would be expected that the larger, more lipophilic indole
45
46 moiety of **1** would confer higher functional affinity than the pyrrole moiety we observe the
47
48 opposite pattern. This is in agreement with our previous finding that the acetamide analogue,
49
50 *N*-((*trans*)-4-(2-(7-cyano-3,4-dihydroisoquinolin-2(1*H*)-yl)ethyl)cyclohexyl)acetamide
51
52 (MIPS1059),²⁰ is a competitive antagonist with significantly higher affinity than **1**.
53
54
55
56
57
58
59
60

1
2
3 Finally, we also synthesized the pyrrolidine analogues from D- (**27b**) and L-proline (**28b**).
4
5 The most striking differences to the pyrrole analogue (**26**) are the introduction of a basic
6
7 nitrogen capable of protonation at physiological pH, the lack of aromaticity and also
8
9 planarity. We hypothesized that introduction of the basic nitrogen would (on protonation)
10
11 result in a strong charge-reinforced hydrogen-bonding interaction with Glu95^{2,65}, thus
12
13 maintaining allosteric pharmacology. However, in both cases of proline analogues, this
14
15 modification resulted in competitive antagonists with a significant increase in functional
16
17 affinity ($K_B = 27$ nM and 46 nM, respectively). There was no significant difference between
18
19 the D- and L-proline analogues. Given the requirement of aromaticity for allosteric
20
21 pharmacology previously discussed for the pyrrole analogue (**26**), it is reasonable to consider
22
23 that the loss of allosteric pharmacology observed for the proline analogues (**27b** and **28b**) is
24
25 also related to a lack of aromaticity, and reaffirms the importance of size and lipophilicity in
26
27 the allosteric pocket. In summary, orthosteric and allosteric pharmacology is most sensitive to
28
29 changes to the tail moiety, where modifications that disrupted its hydrogen-bond donor
30
31 ability, or its size and lipophilicity, generally resulted in loss of allostery, and a concomitant
32
33 gain in affinity. However, fine tuning of the tail group was capable of producing compounds
34
35 with high functional affinity and maintenance of negative allosteric pharmacology, for
36
37 example the 7-azaindole analogue (**25f**).
38
39
40
41
42

43 It must be acknowledged that, while our experimental approach allowed determination of
44
45 parameters of both affinity and negative cooperativity for ligands that display allosteric
46
47 pharmacology, we cannot exclude the possibility that compounds that appear to behave
48
49 competitively with dopamine and [³H]raclopride, may instead display very high negative
50
51 cooperativity. Such high negative cooperativity would be indistinguishable from competitive
52
53 antagonism. Thus, such compounds would not display the partial antagonism of the D₂R of
54
55 ligands conferred by modest negative cooperativity that, in theory, may be beneficial for the
56
57
58
59
60

1
2
3 treatment of the positive symptoms of schizophrenia. Furthermore, it should be noted that **1**
4
5 has the key attributes of a D₂R competitive ligand. In general the structural modifications that
6
7 appear to result in competitive behaviour can be reconciled with our previously described
8
9 mechanism of action for **1** whereby the interaction of the indole moiety of **1** with a secondary
10
11 pocket between TM2 and TM7 confers allosteric pharmacology.
12
13

14 Finally, we have previously provided evidence that **1** acts as a negative allosteric modulator
15
16 at a D₂R dimer. This SAR study has given insight into the structural determinants of the
17
18 allosteric action of **1** at the D₂R and is consistent with the bitopic mode of interaction
19
20 proposed in our first study. However, it was beyond the scope of this study to confirm the
21
22 action of such novel ligands at a D₂R dimer. Future studies will focus on gaining further
23
24 insight into the action of these novel THIQ analogues at D₂R dimers.
25
26
27
28
29

30 **Conclusions**

31
32 We have previously provided evidence that **1** binds in a bitopic manner at one protomer of
33
34 a D₂R dimer and modulates the binding of dopamine at a second protomer. Furthermore, we
35
36 discovered that a hydrogen bond between the indolic NH of **1** and Glu95^{2,65} within the
37
38 secondary pocket is a key ligand-receptor interaction for the allosteric action of **1**. In this
39
40 study we designed and synthesized analogues of **1** to determine the key ligand features
41
42 required for allosteric pharmacology, and successfully identified compounds with high
43
44 affinity and a spectrum of negative cooperativity at the D₂R. The results of this SAR
45
46 approach further validates the bitopic mode of action for **1**, whereby subtle structural
47
48 modifications to any component of the scaffold can have significant consequences on the
49
50 pharmacology of the resulting compound. We focused on synthetic analogues of three main
51
52 portions of the molecule: the THIQ head group; the *trans*-1,4-cyclohexylene spacer group;
53
54 and the 1*H*-indole-2-carboxamide tail group. The most sensitive region to chemical
55
56
57
58
59
60

1
2
3 modifications was the tail group, where any disturbance of the indole NH hydrogen-bond
4 donor ability, or size and lipophilicity, resulted in a change from allosteric to apparent
5 competitive pharmacology. The THIQ head group is crucial for maintaining allosteric
6 pharmacology, with the requirement of a 'small' substituent in the 7-position. When the
7 THIQ head group was replaced with higher affinity 'privileged scaffolds' we observed a
8 change from allosteric to competitive pharmacology. We hypothesize that smaller, lower-
9 affinity orthosteric head groups are more favourable for allosteric pharmacology because they
10 allow correct orientation of the tail group within the secondary binding pocket. We also
11 discovered an intriguing relationship between alkyl chain spacer length and allosteric
12 pharmacology, in which the alternating length of the alkyl spacer may change the orientation
13 of the secondary pharmacophore causing a switch from allosteric to competitive
14 pharmacology. Replacement of the *trans*-1,4-cyclohexylene spacer group with a linear 1,4-
15 butylene or 1,6-hexylene spacer group conferred an increase in functional affinity while
16 maintaining allosteric pharmacology. Finally, replacement of the indole moiety with a 7-
17 azaindole, which presents multiple hydrogen-bond donating and accepting moieties, conferred
18 a 30-fold increase in affinity with maintenance of negative cooperativity with dopamine. The
19 findings of this study provide further insight as to the bitopic binding mode of **1** at the D₂R,
20 and present future opportunities for drug design of bitopic and allosteric molecules for the
21 D₂R.

60

1
2
3 purification. GR grade NH_4OH solution (28% aqueous solution), and LR grade MeOH,
4 EtOAc, CHCl_3 , DCM, Pet. Spirits and MeCN were purchased from Merck and used without
5 further purification. Dry DMF was obtained from an MBraun MB-SPS-800. Davisil® silica
6 gel (40-63 μm), for flash column chromatography was supplied by Grace Davison Discovery
7 Sciences (Victoria, Australia) and deuterated solvents were purchased from Cambridge
8 Isotope Laboratories, Inc. (USA, distributed by Novachem PTY. Ltd, Victoria, Australia).
9
10
11
12
13
14
15

16 All organic extracts collected after aqueous work-up procedures were dried over anhydrous
17 Na_2SO_4 before gravity filtering and concentration *in vacuo* at $\leq 40^\circ\text{C}$ (water bath
18 temperature). Purification using preparative layer chromatography (PLC) was carried out on
19 Analtech preparative TLC plates (200 mm x 200 mm x 2 mm).
20
21
22
23
24

25 All ^1H NMR and ^{13}C NMR spectra (DEPTQ) were recorded on a Bruker Avance III 400
26 Ultrashield Plus spectrometer at 400.13 and 100.62 MHz respectively. Results were recorded
27 as follows: chemical shift values are expressed as δ units acquired in CDCl_3 , or d_6 -DMSO
28 when specified, with tetramethylsilane (0.00 ppm) as reference for ^1H NMR (residual solvent
29 peak as reference for ^{13}C NMR);⁵⁵ multiplicity (singlet (s), doublet (d), triplet (t), pentet (p),
30 quartet (q), broad (br), multiplet (m), doublet of doublets (dd), doublet of triplets (dt), triplet
31 of triplets (tt)); coupling constants (J) in Hertz; and, integration. Thin-layer chromatography
32 was conducted on 0.2 mm plates using Merck silica gel 60 F_{254} . Flash column
33 chromatography was performed using Merck Silica Gel 60, 230-400 mesh ASTM, or using
34 automated CombiFlash® Rf 200 with specified solvents. High resolution mass spectra
35 (HRMS) were obtained on a Waters LCT Premier XE (TOF) using electrospray ionization
36 (ESI) at a cone voltage of 50 V.

23 this composition until 3.8 min, 3.8–4 min 95% buffer A and 5% buffer B, held until 5 min at
24
25 this composition. Mass spectra were acquired in positive and negative ion mode with a scan
26
27 range of 100–1000 *m/z*. UV detection was carried out at 214 and 254 nm. All retention times
28
29 (*t_R*) are quoted in min. Analytical reverse-phase HPLC was performed on a Waters HPLC
30
31 system coupled directly to a photodiode array detector and fitted with a Phenomenex® Luna
32
33 C8 (2) 100 Å column (150 mm × 4.6 mm, 5 μm) using a binary solvent system; solvent A:
34
35 0.1% TFA/H₂O; solvent B: 0.1% TFA/80% CH₃CN/H₂O. Gradient elution was achieved
36
37 using 100% solvent A to 100% solvent B over 20 min at a flow rate of 1 mL/min. All
38
39 compounds subjected to biological testing were found to be >95 % pure by HPLC at two
40
41 wavelengths (λ = 254 and 214 nm).

47
48

49
50 **General Procedure A (Reductive alkylation with *tert*-butyl (*trans*-4-(2-
51
52 oxoethyl)cyclohexyl)carbamate):** The secondary amine (1 eq.) and *tert*-butyl (*trans*-4-(2-
53
54 oxoethyl)cyclohexyl)carbamate³⁰ (**8**, 1 eq.) were taken up in 1,2-DCE (10 mL). NaBH(OAc)₃
55
56 (1.5 eq) was added to the stirred solution at RT under nitrogen. After 16–24 h LCMS
57
58
59
60

1
2
3 confirmed reaction completion. The mixture was diluted with DCM (15 mL), washed with 1
4
5 M K₂CO₃ solution (3 × 20 mL), brine (15 mL), then dried and concentrated *in vacuo*. The
6
7 crude material was purified by flash column chromatography to give the title compound.
8

9
10 **General Procedure B (N-Boc deprotection):** The *N*-Boc protected amine was taken up in
11
12 a mixture of DCM (5 mL) and TFA (1 mL) at RT. After 16 h stirring, the solution was
13
14 diluted with DCM (20 mL) and water (5 mL), followed by dropwise addition of NH₄OH
15
16 solution (approx. 3 mL or until pH 10). The product was extracted with further DCM (2 × 15
17
18 mL), and the combined organic extracts washed with brine (20 mL), dried over Na₂SO₄ and
19
20 concentrated *in vacuo*.
21

22
23 **General Procedure C (N-Boc protection):** To a stirred mixture of the amine (1.2 eq.) in
24
25 DCM (50 mL/g amine) at RT, was slowly added NEt₃ (1.2 eq.), followed by dropwise
26
27 addition of a solution of Boc₂O (1 eq.) in DCM (5 mL/g Boc₂O). After 1 – 24 h, the reaction
28
29 was washed with 1 M KHSO₄ (3 × 30 mL), brine, dried and concentrated *in vacuo*.
30
31

32 **General Procedure D (Activation of alcohols to corresponding methanesulfonate**
33
34 **esters):** To a solution of the alcohol (1 eq.) in DCM (20 mL) was added NEt₃ (2 eq.). After 5
35
36 min, a solution of methanesulfonyl chloride (1.2 eq.) in DCM (5 mL) was added dropwise.
37
38 After 16 h stirring at RT, the solution was washed with 1 M NaOH (20 mL), 1 M KHSO₄ (20
39
40 mL), brine, then dried and concentrated *in vacuo*.
41
42

43 **General Procedure E (HCTU-mediated amide coupling):** The amine (1 eq.) was taken
44
45 in dry DMF (5-10 mL), and under N₂ at RT was added the carboxylic acid (1.2 eq.) followed
46
47 by HCTU (1.5 eq.) and DIPEA (5 eq.). After 16 h, the solution was concentrated *in vacuo*,
48
49 then 2 M NaHCO₃ (20 mL) was added, and the product extracted with EtOAc (20 mL). The
50
51 organic layer was then washed with 2 M NaHCO₃ (2 × 20 mL), brine (20 mL), then dried and
52
53 concentrated *in vacuo*. The product was then purified by flash column chromatography in
54
55 specified conditions.
56
57

3 **2,3,4,5-Tetrahydro-1H-benzo[c]azepin-1-one (3).**³¹ 1-Tetralone (**2**) (1.00 g, 6.84 mmol)
4 was taken up in conc. HCl (12 mL) with ice cooling to 0 °C, and sodium azide (889 mg, 13.7
5 mmol) was slowly added portionwise to maintain 0 °C. After complete addition, the mixture
6 was warmed to RT, then heated at 50 °C for 16 h. The mixture was then poured into ice-cold
7 water (15 mL), and made alkaline with slow addition of 1 M K₂CO₃ to pH 10. The product
8 was then extracted with DCM (3 × 30 mL), and the organic extracts were combined, dried
9 and concentrated *in vacuo*. The product was purified by flash column chromatography
10 (EtOAc) to give pale yellow needles (675 mg, 61%, lit.³¹ 52%). ¹H NMR δ 7.71 (dd, *J* =
11 7.5/1.4 Hz, 1H), 7.51 (s, 1H), 7.40 (td, *J* = 7.4/1.6 Hz, 1H), 7.34 (td, *J* = 7.5/1.4 Hz, 1H), 7.19
12 (dd, *J* = 7.4/0.8 Hz, 1H), 3.13 (q, *J* = 6.5 Hz, 2H), 2.87 (t, *J* = 7.1 Hz, 2H), 2.02 (p, *J* = 6.8

29 **2,3,4,5-Tetrahydro-1H-benzo[c]azepine (4).**⁵⁶ Lithium aluminium hydride (177 mg, 4.65
30 mmol) was taken in dry THF (10 mL), and to the stirred solution under N₂ at 0 °C was slowly
31 added a solution of 2,3,4,5-tetrahydro-1H-benzo[c]azepin-1-one (**3**) (250 mg, 1.55 mmol) in
32 dry THF (5 mL). The solution was stirred at RT for 30 min, then heated to reflux. After 16 h,
33 the mixture was cooled on ice, and water (15 mL) was slowly added. The solids were filtered
34 through a plug of Celite, and then washed with Et₂O (30 mL). The product was then further
35 extracted with Et₂O (2 × 20 mL), and the combined extracts were dried and concentrated *in*
36 *vacuo* to reveal the title compound as a clear oil (197 mg, 86%, lit.⁵⁶ 60%) which required no
37 further purification. ¹H NMR δ 7.17 – 7.07 (m, 4H), 3.92 (s, 2H), 3.24 – 3.15 (m, 2H), 2.98 –
38 2.89 (m, 2H), 1.76 – 1.66 (m, 2H), 1.41 (s, 1H). ¹³C NMR δ 143.1 (C), 143.0 (C), 129.3

After 1 h, water (20 mL) was added, then the organic layer washed with 1 M K₂CO₃ (2 × 20 mL), brine (20 mL) and dried over Na₂SO₄ and concentrated *in vacuo*. The product was purified by flash column chromatography

(EtOAc, gradient to 20:1, EtOAc:MeOH, v/v) to give **32** as a white solid (27 mg, 41%). ¹H NMR δ 9.52 (br s, 1H), 7.40 (dd, *J* = 7.9/1.6 Hz, 1H), 7.33 (s, 1H), 7.19 (d, *J* = 7.9 Hz, 1H), 6.90 (td, *J* = 2.7/1.3 Hz, 1H), 6.51 (ddd, *J* = 3.7/2.5/1.3 Hz, 1H), 6.22 (dt, *J* = 3.7/2.6 Hz, 1H), 5.66 (d, *J* = 8.2 Hz, 1H), 3.96 – 3.81 (m, 1H), 3.63 (s, 2H), 2.95 (t, *J* = 5.8 Hz, 2H), 2.75 (t, *J* = 5.8 Hz, 2H), 2.61 – 2.49 (m, 2H), 2.13 – 2.01 (m, 2H), 1.88 – 1.80 (m, 2H), 1.52 (dd, *J* = 15.1/6.8 Hz, 2H), 1.41 – 1.07 (m, 5H). ¹³C NMR δ 160.4 (C), 140.4 (C), 136.4 (C), 130.6 (CH), 129.8 (CH), 129.7 (CH), 126.4 (C), 121.3 (CH), 119.3 (C), 109.8 (CH), 109.6 (C), 108.3 (CH), 56.2 (CH₂), 55.7 (CH₂), 50.4 (CH₂), 48.6 (CH), 35.4 (CH), 34.1 (CH₂), 33.4 (CH₂), 32.0 (CH₂), 29.5 (CH₂). HRMS (*m/z*): [MH]⁺ calcd. for C₂₃H₂₈N₄O, 377.2336; found 377.2348.

(*R*)-*N*-(*trans*-4-(2-(7-Cyano-3,4-dihydroisoquinolin-2(1*H*)-yl)ethyl)cyclohexyl)pyrrolidine-2-carboxamide (27b). Following General Procedure E using 2-(2-((*trans*)-4-aminocyclohexyl)ethyl)-1,2,3,4-tetrahydroisoquinoline-7-carbonitrile (**11a**) as the amine, and (*R*)-1-(*tert*-butoxycarbonyl)pyrrolidine-2-carboxylic acid. Purification by flash column chromatography (10:1, EtOAc:MeOH, v/v) afforded **27b** as a pale yellow oil, which was then taken up in DCM (5 mL) and deprotected following General Procedure B. The product was purified by flash column chromatography (7:1:0.1, CHCl₃:MeOH:NH₄OH) to give the title compound as a pale yellow oil (18 mg, 15%). ¹H NMR δ 7.43 (d, *J* = 8.6 Hz, 1H), 7.40 (dd, *J* = 7.9/1.6 Hz, 1H), 7.32 (s, 1H), 7.19 (d, *J* = 7.9 Hz, 1H), 3.72 – 3.64 (m, 2H), 3.60 (s, 2H), 3.04 – 2.82 (m, 4H), 2.72 (t, *J* = 5.9 Hz, 2H), 2.58 – 2.47 (m, 2H), 2.16 – 2.06 (m, 1H), 1.99 – 1.83 (m, 4H), 1.83 – 1.75 (m, 2H), 1.73 – 1.64 (m, 2H), 1.50 (dd, *J* = 15.1/6.9 Hz, 2H), 1.33 – 1.26 (m, 1H), 1.21 – 1.06 (m, 4H). ¹³C NMR δ 174.4 (C), 140.5 (C), 136.5 (C), 130.5 (CH), 129.7 (CH), 129.6 (CH), 119.3 (C), 109.5 (CH), 60.7 (CH), 56.2 (CH₂), 55.8 (CH₂), 50.4 (CH₂), 47.9 (CH), 47.4 (CH₂), 35.4 (CH), 34.2 (CH₂), 33.2 (CH₂)*, 33.1 (CH₂)*, 32.04

(CH₂)*, 32.01 (CH₂)*, 30.9 (CH₂), 29.6 (CH₂), 26.3 (CH₂). HRMS (*m/z*): [MH]⁺ calcd. for C₂₃H₃₂N₄O, 381.2649; found 381.2656. *Extra signals due to different rotameric forms.

(S)-N-(trans-4-(2-(7-Cyano-3,4-dihydroisoquinolin-2(1H)-yl)ethyl)cyclohexyl)pyrrolidine-2-carboxamide (28b). Following General Procedure E using 2-(2-((*trans*)-4-aminocyclohexyl)ethyl)-1,2,3,4-tetrahydroisoquinoline-7-carbonitrile (**11a**) as the amine, and (*S*)-1-(*tert*-butoxycarbonyl)pyrrolidine-2-carboxylic acid. Purification by flash column chromatography (10:1, EtOAc:MeOH, v/v) afforded **28b** as a pale yellow oil, which was then taken up in DCM (5 mL) and deprotected following General Procedure B. The product was purified by flash column chromatography (20:1:0.01, CHCl₃:MeOH:NH₄OH to 5:1:0.1 CHCl₃:MeOH:NH₄OH) to give the title compound as a pale yellow oil (22 mg, 23%). ¹H NMR δ 7.46 (d, *J* = 8.6 Hz, 1H), 7.40 (dd, *J* = 7.9/1.6 Hz, 1H), 7.32 (s, 1H), 7.19 (d, *J* = 7.9 Hz, 1H), 3.74 (dd, *J* = 9.1/5.4 Hz, 1H), 3.70 – 3.61 (m, 1H), 3.60 (s, 2H), 3.06 – 2.98 (m, 1H), 2.98 – 2.85 (m, 3H), 2.72 (t, *J* = 5.9 Hz, 2H), 2.58 – 2.50 (m, 2H), 2.25 – 2.10 (m, 2H), 1.98 – 1.85 (m, 3H), 1.84 – 1.76 (m, 2H), 1.76 – 1.65 (m, 2H), 1.50 (dd, *J* = 15.2/6.9 Hz, 2H), 1.36 – 1.23 (m, 1H), 1.23 – 1.05 (m, 4H). ¹³C NMR δ 174.0 (C), 140.5 (C), 136.5 (C), 130.5 (CH), 129.7 (CH), 129.7 (CH), 119.3 (C), 109.5 (C), 60.7 (CH), 56.2 (CH₂), 55.8 (CH₂), 50.4 (CH₂), 48.0 (CH), 47.3 (CH₂), 35.4 (CH), 34.2 (CH₂), 33.3 (CH₂)*, 33.1 (CH₂)*, 32.04 (CH₂)*, 32.00 (CH₂)*, 31.0 (CH₂), 29.6 (CH₂), 26.2 (CH₂). HRMS (*m/z*): [MH]⁺ calcd. for C₂₃H₃₂N₄O, 381.2649; found 381.2658. *Extra signals due to different rotameric forms.

Pharmacological Characterization

Cell Lines and Transfection: FlpIn CHO cells (Invitrogen, Carlsbad, USA) were grown in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum and maintained at 37 °C in a humidified incubator containing 5% CO₂. The FlpIn CHO cells were transfected with the pOG44 vector encoding Flp recombinase and the pDEST vector encoding the wild-type long isoform of the human D₂ receptor (D_{2L}R) at a ratio of 9:1 using

1
2
3 polyethylenimine as transfection reagent. 24 h after transfection the cells were subcultured
4
5 and the medium was supplemented with 700µg/ml HygroGold as selection agent. Cells were
6
7 grown and maintained in DMEM containing 20 mM HEPES, 5% fetal bovine serum and 200
8
9 µg/mL Hygromycin-B. Cells were maintained at 37 °C in a humidified incubator containing
10
11 5% CO₂, 95% O₂. For radioligand binding assays when cells were approximately 90%
12
13 confluent, they were harvested and centrifuged (300 g, 3 min). The resulting pellet was
14
15 resuspended in assay buffer (20 mM HEPES, 6 mM MgCl₂, 1 mM EGTA, 1 mM EDTA; pH
16
17 7.4), and the centrifugation procedure repeated. The intact cell pellet was then resuspended in
18
19 assay buffer and homogenised using a Polytron homogeniser for three 10-second intervals on
20
21 the maximum setting, with 30-second periods on ice between each burst. The homogenate
22
23 was made up to 30 mL and centrifuged (350 g, 5 min, 4 °C), the pellet discarded and the
24
25 supernatant recentrifuged at 30,000 g for 1 hour at 4 °C. The resulting pellet was resuspended
26
27 in 5 mL assay buffer and the protein content determined using the method of Bradford. The
28
29 homogenate was then separated into 1 mL aliquots and stored frozen at -80 °C until required
30
31 for binding assays.
32
33
34
35
36
37

38
39 *[³H]raclopride binding assay:* Cell membranes (D₂L-Flp-In CHO, 10 µg) were incubated
40
41 with varying concentrations of test compound in binding buffer (20 mM HEPES, 100 mM
42
43 NaCl, 6 mM MgCl₂, 1 mM EGTA, 1 mM EDTA; pH 7.4) containing 0.5 nM of
44
45 [³H]raclopride to a final volume of 0.3 mL and incubated at 37 °C for 3 h. Binding was
46
47 terminated by fast flow filtration over GF/B membrane unifier plates (Perkin Elmer) using a
48
49 Uniplate 96-well harvester (Perkin Elmer) followed by five washes with ice-cold 0.9% NaCl.
50
51 Bound radioactivity was measured in a MicroBeta² LumiJET microbeta counter (Perkin
52
53 Elmer).
54
55
56
57
58
59
60

1
2
3 *ERK1/2 phosphorylation assay:* FlpIn CHO cells stably expressing the D_{2L}R were seeded
4 into 96-well plates at a density of 50,000 cells/well. After 5-7 h, cells were washed with
5 phosphate-buffered saline (PBS) and incubated in serum-free DMEM overnight before
6 assaying. Initially, time-course experiments were conducted at least twice for each ligand to
7 determine the time required to maximally promote ERK1/2 phosphorylation via the
8 dopamine D_{2L}R. Concentration-response experiments in the absence or presence of ligand
9 were performed at 37 °C in a 200 µL total volume of DMEM containing 20 mM HEPES and
10 0.1 % ascorbic acid. Concentration-response stimulation or inhibition curves were generated
11 by exposure of the cells to antagonist ligand for 30 min and then dopamine for 5 min.
12 Stimulation of cells was terminated by the removal of media and the addition of 100 µL of
13 SureFire™ lysis buffer to each well. The plate was agitated for 1-2 min. A 4:1 v/v dilution of
14 Lysate:SureFire™ activation buffer was made in a total volume of 50 µL. A 1:100:120 v/v
15 dilution of AlphaScreen™ beads:activated lysate mixture:SureFire™ reaction buffer in an 11
16 µL total volume was then transferred to a white opaque 384-well Proxiplate™ in the dark.
17 This plate was then incubated in the dark at 37 °C for 1.5 h after which time the fluorescence
18 signal was measured by a Fusion-TM plate reader (PerkinElmer), using standard
19 AlphaScreen™ settings. Data were normalized to the response generated by 10% fetal bovine
20 serum.

45

46 *Data Analysis:*

47
48 *Radioligand binding data:* Competition-binding curves between [³H]raclopride and **1** could
49 be fit to the allosteric ternary complex model using the following equation⁶:
50
51
52
53
54
55
56
57
58
59
60

$$Y = \frac{\frac{[A]}{K_A}}{\frac{[A]}{K_A} + \left(\frac{1 + \frac{[B]}{K_B}}{1 + \alpha \frac{[B]}{K_B}} \right)} \quad (1)$$

Where Y is percentage (vehicle control) binding; [A] and [B] are the concentrations of [³H]raclopride and **1**, respectively; K_A and K_B are the equilibrium dissociation constants of [³H]raclopride and **1**, respectively; α is the cooperativity between **1** and [³H]raclopride. Values of $\alpha > 1$ denote positive cooperativity; values < 1 (but > 0) denote negative cooperativity, and values = 1 denote neutral cooperativity.

Functional data: A logistic equation of competitive agonist-antagonist interaction was globally fitted to data from functional experiments measuring the interaction between dopamine and all analogues of **1**:

$$Response = Bottom + \frac{(E_{max} - Bottom)}{1 + \left(\frac{10^{-pEC_{50}} \left[1 + \left(\frac{[B]}{10^{-pA_2}} \right)^s \right]^{nH}}{[A]} \right)} \quad (2)$$

Where s represents the Schild slope for the antagonist, and pA_2 represents the negative logarithm of the molar concentration of antagonist that makes it necessary to double the concentration of agonist needed to elicit the original submaximal response obtained in the absence of antagonist.

Functional data describing the interaction between all **1** analogues and dopamine analyzed according to the allosteric ternary complex model.

$$E = \frac{E_m \cdot [A]^{nH}}{[A]^{nH} + [EC_{50}]^{nH} \left(\frac{1 + \frac{[B]}{K_B}}{1 + \frac{\alpha [B]}{K_B}} \right)} \quad (3)$$

1
2
3 Where E_m is the maximum possible cellular response, $[A]$ and $[B]$ are the concentrations of
4 orthosteric and allosteric ligands, respectively, and K_B are the equilibrium dissociation
5 constant of the orthosteric and allosteric ligands, $\alpha\beta$ is a composite cooperativity parameter
6 between the orthosteric and allosteric ligand that includes effects upon orthosteric ligand
7 affinity and efficacy and nH is the Hill slope of the orthosteric agonist concentration-response
8 curve. Values of α and/or β greater than 1 denote allosteric potentiation, whereas values less
9 than 1 (but greater than 0) denote allosteric inhibition.

10
11 For each of the compounds the two equations (models) were then compared for their fit
12 using an extra-sum-of-squares F test, whereby the simpler model was selected unless the P
13 value was less than 0.05.

Abbreviation List

2-MPP - 1-(2-methoxyphenyl)piperazine

2,3-DCPP - 1-(2,3-dichlorophenyl)piperazine

D₂R – dopamine D₂ receptor

DA – dopamine

DIPEA - *N,N*-diisopropylethylamine

HCTU - *O*-(6-chlorobenzotriazol-1-yl)-*N,N,N',N'*-tetramethyluronium hexafluorophosphate

THIQ - tetrahydroisoquinoline

TM - transmembrane

Schemes

Scheme 1. Synthesis of 2,3,4,5-tetrahydro-1*H*-benzo[*c*]azepine.^a

^aReagents and conditions: (a) concentrated HCl, NaN₃, 0-50 °C, 16 h, basic workup, 61%; (b) LiAlH₄, THF, reflux, 16 h, 86%.

Scheme 2. Synthesis of the *trans*-cyclohexylene spacer unit and compounds with modifications to the 7-CTHIQ head group.^a

^aReagents and conditions: (a) 10% Pd/C, H₂, 60 psi, rt, 3 d, then; EtOH, conc. HCl, reflux, 2 h, 81%; (b) Boc₂O, NEt₃, DCM, rt, 2 h, 96%; (c) DIBALH, toluene, -78 °C, 30 min, 99%; (d) NaBH(OAc)₃, 1,2-DCE, RT, 16-24 h, 14-91%; (e) TFA, DCM, RT, 16 h, followed by NH₄OH, 80-99% (**11a, c-h** as free base; **11b** as dihydrochloride salt following acidification with HCl/Et₂O) and 4 M HCl/1,4-dioxane, rt, 95-100% (**11i-j** as trihydrochloride salt); (f) 1H-indole-2-carboxylic acid, HCTU, DIPEA, DMF, RT, 16 h, 22-81%.

Scheme 3. Synthesis of **1** derivatives (**18a-d**) with polymethylene spacer units.^a

^aReagents and conditions: (a) Boc₂O, Et₃N, DCM, RT, 24 h, 47–93%; (b) MsCl, Et₃N, DCM, 16 h, RT, 86–93%; (c) **9a**, K₂CO₃, MeCN, reflux, 16 h, 41%; (d) **9a**, NEt₃, DCM, RT, 16 h, 14–52%; (e) TFA, DCM, RT, 2-16h, followed by NH₄OH, 46-99%; (f) 1*H*-indole-2-carboxylic acid, HCTU, DIPEA, DMF, RT, 16 h, 45–79%.

Scheme 4. Synthesis of the *N*-methylated indole-2-carboxamide analogue of **1** (**23**).^a

^aReagents and conditions: (a) MeI, NaH, DMF, 0 °C, 3d, 36%; (b) DIBAL-H, PhMe, -78 °C, 100%; (c) **9a**, NaBH(OAc)₃, 1,2-DCE, RT, 37%; (d) TFA, DCM, RT, 16 h, followed by NH₄OH, 98%; (e) indole-2-carboxylic acid, HCTU, DIPEA, DMF, RT, 16 h, 34%.

Scheme 5. Synthesis of analogues of **1** with modifications to the hydrogen-bond donating ability of the *1H*-indole-2-carboxamide tail group (**25a-f**).^a

^aReagents and conditions: (a) benzofuran-2-carboxylic acid (**24a**), benzoxazole-2-carboxylic acid potassium salt (**24b**), indene-2-carboxylic acid (**24c**), 1-methylindole-2-carboxylic acid (**24d**), 1*H*-benzimidazole-2-carboxylic acid (**24e**), pyrrolo[2,3-*b*]pyridine-2-carboxylic acid (**24f**), HCTU, DIPEA, DMF, RT, 16 h, 16-79%.

Scheme 6. Synthesis of the ring-deleted, pyrrole analogue of **1** (**26**), and the D- (**27b**) and L-proline (**28b**) analogues of **1** to investigate the impact of steric bulk and ionization on the tail group.^a

^aReagents and conditions: (a) pyrrole-2-carboxylic acid, EDCI, DMAP, DCM, RT, 1 h, 41%; (b) (i) *N*-Boc-D-proline (for **27a**) or *N*-Boc-L-proline (for **28b**), HCTU, DIPEA, DMF, RT, 16 h; (ii) TFA, DCM, RT, 16 h, followed by NH₄OH, 15-23%.

Figures and captions

Figure 1. The proposed binding mode of **1**, which displays allosteric pharmacology despite containing structural features of a competitive ligand. **1** was found to act via a novel mechanism, engaging one protomer of a D₂R dimer in a bitopic mode, and negatively modulating dopamine (DA) binding and function at the other protomer.²⁰ The red box represents the orthosteric-binding portion, while the green oval represents the allosteric-binding portion of **1**.

Figure 2. General overview of structural modifications of **1** investigated in this study.

5 a) Competition binding experiments between analogues of **1** and the radiolabeled antagonist
6 [³H]raclopride using membranes of FlpIn CHO expressing the hD_{2L}R reveal that some compounds
7 (such as **12e** shown here) were able to fully inhibit raclopride binding consistent with a competitive
8 interaction. These data could be used to derive a value of affinity (K_B). Other compounds, exemplified
9 by **1**, were unable to fully displace [³H]raclopride binding consistent with an allosteric interaction.
10 These data could be fit with an allosteric ternary complex model to derive values of affinity (K_B) and
11 negative cooperativity with [³H]raclopride.
- 12 b) The action of increasing concentrations of **1** upon a dopamine concentration-response curve was
13 measured in an assay measuring ERK1/2 phosphorylation using whole cells expressing the hD_{2L}R.
14 Increasing concentrations of **1** caused a limited dextral displacement of the dopamine dose-response
15 curve and data were analyzed according to an operational model of allosterism.
- 16 c) The action of increasing concentrations of **12e** upon a dopamine concentration-response curve was
17 measured in an assay measuring ERK1/2 phosphorylation using whole cells expressing the hD_{2L}R.
18 Increasing concentrations of **12e** caused a limitless dextral displacement of the dopamine dose-response
19 curve and data were analyzed according to a Gaddum/Schild model of competitive pharmacology.
