## Abstract

Human milk oligosaccharides (HMOs) afford many health benefits to breast-fed infants, such as protection against infection and regulation of the immune system, through the formation of non-covalent interactions with protein receptors. However, the molecular details of these interactions are poorly understood. Here, we describe the application of catch-and-release electrospray ionization mass spectrometry (CaR-ESI-MS) for screening natural libraries of HMOs against lectins. The HMOs in the libraries were first identified based on molecular weights (MWs), ion mobility separation arrival times (IMS-ATs) and collision-induced dissociation (CID) fingerprints of their deprotonated anions. The libraries were then screened against lectins and the ligands identified from the MWs, IMS-ATs and CID fingerprints of HMOs released from the lectin in the gas phase. To demonstrate the assay, four fractions, extracted from pooled human milk and containing  $\geq 35$  different HMOs, were screened against a C-terminal fragment of human galectin-3 (hGal-3C), for which the HMO specificities have been previously investigated, and a fragment of the blood group antigen-binding adhesin (BabA) from *Helicobacter pylori*, for which the HMO specificities have not been previously established. The structures of twenty-one ligands, corresponding to both neutral and acidic HMOs, of hGal-3C were identified; all twenty-one were previously shown to be ligands for this lectin. The presence of HMO ligands at six other MWs was also ascertained. Application of the assay to BabA revealed nineteen specific HMO structures that are recognized by the protein and HMO ligands at two other MWs. Notably, it was found that BabA exhibits broad specificity for HMOs, and recognizes both neutral HMOs, including non-fucosylated ones, and acidic HMOs. The results of competitive binding

experiments indicate that HMOs can interact with BabA at previously unknown binding sites. The affinities of eight purified HMOs for BabA were measured by ESI-MS and found to be in the  $10^3 \text{ M}^{-1}$  to  $10^4 \text{ M}^{-1}$  range.

## Introduction

Human milk, in addition to being an essential source of nutrition, provides infants with many important health benefits.<sup>1,2</sup> Human milk contains a variety of active components, including proteins, glycoproteins and fat globules.<sup>3</sup> Every liter of human milk also contains approximately 5 g to 25 g of unconjugated oligosaccharides, known as human milk oligosaccharides (HMOs).<sup>4</sup> Studies have shown that HMOs afford health benefits to breast-fed infants through several mechanisms.<sup>5-7</sup> They are known to have immune-stimulating effects and can influence the composition of microbiota in the gut and promote the growth of beneficial microorganisms.<sup>8-10</sup> HMOs can also protect newborns against infectious diseases by interfering with the binding of pathogenic bacteria and their toxins and viruses to intestinal epithelial cells.<sup>11</sup>

Central to the varied biological roles played by HMOs are the specific non-covalent interactions they form with endogenous and exogenous protein receptors. While their importance is well appreciated, the molecular details of these interactions are poorly understood. The large number of HMO structures found in human milk, including the presence of many structural isomers, and their wide ranging concentrations ( $\sim 0.01 \text{ g L}^{-1}$  to  $\sim 2 \text{ g L}^{-1}$ ) represent significant challenges to the comprehensive analysis of HMO interactions with proteins.<sup>4,12</sup> Of the more than two hundred known HMOs, fewer than fifty are commercially available.<sup>13-17</sup> Given the limited availability of purified HMOs, the use of mixtures of HMO, extracted directly from milk, is an attractive alternative for protein-HMO interaction studies. However, there are few screening technologies that are readily applied to natural libraries. One approach, pioneered by Cummings and co-workers, involves the use of shotgun glycan microarrays, which employ fractions of

1  
2  
3 HMOs, purified from human milk, that are chemically modified and immobilized on a solid  
4 surface.<sup>18-20</sup> The use of HMO glycan microarrays allows for the rapid profiling of HMO binding  
5  
6 properties of lectins and the discovery of new protein-HMO interactions that might be relevant to  
7  
8 human health. However, the derivatization of HMOs at the reducing end glucose is a drawback  
9  
10 to this approach since the terminal lactose moiety is often implicated in the binding of HMOs to  
11  
12 lectins.<sup>21</sup>

13  
14 Electropray ionization mass spectrometry (ESI-MS) is an attractive alternative to glycan  
15  
16 microarrays for screening carbohydrate libraries against lectins *in vitro* and is particularly well  
17  
18 suited for the study of HMO interactions since there is no requirement for labeling or  
19  
20 immobilization of the oligosaccharides, which may influence their binding properties.<sup>21</sup> Direct  
21  
22 detection and quantification of free and ligand-bound proteins ions by ESI-MS enables the  
23  
24 binding stoichiometry and affinity of protein-carbohydrate interactions to be established.<sup>22-26</sup>  
25  
26 Moreover, because it is possible to monitor multiple binding equilibria simultaneously, ESI-MS  
27  
28 is also amenable to screening carbohydrate libraries.<sup>27</sup> In cases where the protein-carbohydrate  
29  
30 complexes can't be detected or reliably quantified, library screening can be performed using a  
31  
32 catch-and-release (CaR)-ESI-MS format, whereby ligands are identified following their release,  
33  
34 as ions, from protein-ligand complexes upon collisional activation in the gas phase.<sup>27</sup> The assay  
35  
36 is rapid, sensitive and label- and immobilization-free and, although not quantitative, can be used  
37  
38 to identify the highest affinity ligands and to guide follow-up quantitative binding  
39  
40 measurements.<sup>27</sup>

41  
42 The CaR-ESI-MS assay has been previously used to screen a variety of defined  
43  
44 oligosaccharide libraries, including free HMOs, and shown to successfully identify the highest  
45  
46 affinity ligands in libraries containing in excess of two hundred different components.<sup>28-34</sup> Here,  
47  
48  
49  
50

we describe the application of the assay for screening mixtures of HMOs, extracted from pooled human milk, against lectins to identify specific ligands. To our knowledge, this represents the first demonstration of CaR-ESI-MS for screening natural libraries for protein interactions. The main advantage of using natural HMO libraries, compared to the libraries of purified HMOs, is the larger number and diversity of structures that are present, in particular the inclusion of larger oligosaccharides, which are not commercially available. A disadvantage is that it may not be possible to unambiguously assign the structures of all the extracted HMOs. However, even in cases where the exact structure is not known, the monosaccharide composition of the HMO ligand(s) can be readily established.

In the present study, the feasibility of using the CaR-ESI-MS assay to screen natural libraries of HMOs was demonstrated using a C-terminal fragment of human galectin-3 (hGal-3C), which contains the carbohydrate recognition domain, as a model HMO-binding lectin. The affinities of thirty-two free (unmodified) HMOs for hGal-3C were recently measured and these binding data served to validate the majority of the interactions identified by CaR-ESI-MS for the HMO libraries.<sup>21</sup> The assay was then used to screen the HMO libraries against a truncated form of the blood group antigen-binding adhesin (BabA) from *Helicobacter pylori* to evaluate its HMO specificities. This adhesin, one of approximately thirty outer membrane proteins, plays an important role in the association of *H. pylori* to the gastric mucosa.<sup>35,36</sup> BabA is known to recognize the fucosylated Lewis b histo-blood group antigen, Le<sup>b</sup> and H1 terminal fucose residues on blood group O (H antigen), A and B antigens, salivary nonmucin glycoprotein gp-340, salivary mucin MUC5B and proline-rich glycoprotein.<sup>35,36</sup> Fucosylated glycans have been shown to inhibit *H. pylori* adhesion to human gastric tissue,<sup>37</sup> however, the HMO specificities of the adhesins have not been previously determined. Quantitative ESI-MS binding measurements,

performed on a subset of HMOs identified as ligands for BabA by the CaR-ESI-MS assay, served to validate the screening results. Competitive binding measurements were also carried out to establish whether BabA possesses previously unknown HMO binding sites.

## Experimental Section

### Proteins

The recombinant fragment of the C-terminus (residues 107–250) of human galectin-3 (hGal-3C, MW 16,330 Da) was a gift from Prof. C. Cairo (University of Alberta) and the recombinant truncated form (residues 21–547) of the blood group antigen-binding adhesin (BabA) from *Helicobacter pylori* strain J99 (BabA<sub>547</sub>, MW 58,211 Da) was produced and purified as described elsewhere.<sup>38</sup> Lysozyme (MW 14,310 Da), which served as the reference protein (P<sub>ref</sub>), was purchased from Sigma-Aldrich Canada (Oakville, Canada). Each protein was dialyzed against 200 mM aqueous ammonium acetate (pH 6.8), concentrated using 10 kDa MW cut-off Amicon Ultra-4 centrifugal filters (Millipore Corp, Bedford, MA), and stored at -20 °C until used.

### Human milk oligosaccharides

The structures of the pure HMOs are listed Table S1, Supporting Information. **HMO1** (MW 488.17 Da), **HMO2** (MW 488.17 Da), **HMO12** (MW 853.31 Da), **HMO13** (MW 853.31 Da), **HMO17** (MW 998.34 Da), **HMO20** (MW 999.36 Da), **HMO21** (MW 1072.38 Da), **HMO23** (MW 1144.40 Da), **HMO24** (MW 1144.40 Da), **HMO27** (MW 1364.50 Da) and **HMO28** (MW 1438.51 Da), **HMO29** (MW 545.48 Da), **HMO30** (MW 691.25 Da) and **HMO31** (MW 1056.39 Da) were purchased from Elicityl SA (Crolles, France); **HMO3** (MW 633.21 Da), **HMO4** (MW 633.21 Da), **HMO5** (MW 634.23 Da), **HMO6** (MW 707.25 Da), **HMO7** (MW 707.25 Da), **HMO8** (MW 779.27 Da), **HMO9** (MW 853.31 Da), **HMO10** (MW 853.31 Da), **HMO11** (MW

853.31 Da), **HMO14** (MW 998.34 Da), **HMO15** (MW 998.34 Da), **HMO16** (MW 998.34 Da), **HMO18** (MW 999.36 Da) and **HMO26** (MW 1364.50 Da) were purchased from IsoSep (Tullinge, Sweden); **HMO19** (MW 999.36 Da) and **HMO22** (MW 1072.38 Da) from Dextra (Reading, UK); **HMO25** (MW 1289.44 Da) was purchased from CarboSynth (Compton, UK). Stock solutions of each HMO were prepared by dissolving a known mass of the oligosaccharide in ultrafiltered water (Milli-Q, Millipore, Billerica, MA) to give a final concentration of 1 mM. All of the stock solutions were stored at -20 °C until used.

### HMO fractions

Fourteen HMO fractions (designated as *Fraction 1 – Fraction 14*) were produced from pooled HMOs (pHMOs) originally isolated from human milk pooled from over 50 different donors with term infants. First, after centrifugation of the pooled human milk, the lipid layer was removed and proteins were precipitated from the aqueous phase by addition of ice-cold ethanol and subsequent centrifugation. Ethanol was removed from the HMO-containing supernatant by roto-evaporation. Lactose and salts were removed by gel filtration chromatography over a BioRad P2 column (100 cm x 16 mm, Bio-Rad, Hercules, California, USA) using a semi-automated fast protein liquid chromatography (FPLC) system. Second, pHMOs were separated by charge using anion exchange chromatography on an anion exchange column QAE Sephadex A-25 (Sigma-Aldrich, St. Louis, USA). Lyophilised pooled HMO were dissolved in 2 mM Tris and applied to equilibrated columns. Neutral HMOs were eluted with 2 mM Tris. Acidic HMOs were eluted with 2 mM Tris containing 200 mM NaCl. Afterwards, Tris and NaCl were removed from the neutral and acidic HMO fractions by gel filtration chromatography over a Bio-Gel P-2 gel filtration chromatography column (100 cm x 16 mm). Third, neutral and acidic HMO fractions

were further separated by size using Bio-Gel P-2 gel filtration chromatography (160 cm x 16 mm) with 10 mL subfraction resolution. All fractions were lyophilized for future use.

To prepare stock solutions, *Fraction 1-Fraction 14* (*Fraction 1* (1.08 mg), *Fraction 2* (0.95 mg), *Fraction 3* (1.77 mg), *Fraction 4* (1.05 mg), *Fraction 5* (0.95 mg), *Fraction 6* (1.33g), *Fraction 7* (1.00 mg), *Fraction 8* (0.55 mg), *Fraction 9* (0.69 mg), *Fraction 10* (1.20 mg), *Fraction 11* (0.51 mg), *Fraction 12* (0.29 mg), *Fraction 13* (2.11 mg) and *Fraction 14* (0.85 mg)) were dissolved separately in 40 mL Milli-Q water. Following a 100-fold dilution with Milli-Q water, each of the stock solutions was stored at -20 °C until used. Given that, based on ESI-MS analysis, some of the fractions had similar compositions, *vide infra*, these were pooled to give four new fractions, designated as: *Fr1* (*Fraction 1*), *Fr2* (*Fractions 2-5*), *Fr3* (*Fractions 6-10*), *Fr4* (*Fractions 11-14*).

### Mass spectrometry

All CaR-ESI-MS measurements were carried out in negative ion mode using a Synapt G2 ESI quadrupole-ion mobility separation-time-of-flight (Q-IMS-TOF) mass spectrometer (Waters, Manchester, UK), equipped with a nanoflow ESI (nanoESI) source. NanoESI tips were produced in-house from borosilicate capillaries (1.0 mm o.d., 0.78 mm i.d.) pulled to ~5  $\mu\text{m}$  outer-diameter using a P-1000 micropipette puller (Sutter Instruments, Novato, CA). To perform nanoESI, a platinum wire was inserted into the nanoESI tip and a voltage of -1.0 kV was applied. A Cone voltage of 25 V was used and the source block temperature was maintained at 50 °C. For the CaR-ESI-MS measurements, a Trap voltage of 5 V, and Transfer voltage between 10 V and 80 V, was used. Argon was used in the Trap and Transfer ion guides at pressures of  $2.22 \times 10^{-2}$  mbar and  $3.36 \times 10^{-2}$  mbar, respectively. The helium chamber preceding the traveling wave IMS (TWIMS) device was maintained at 7.72 mbar. The IMS parameters, which were optimized for

each HMO MW, were: 2 mL min<sup>-1</sup> Trap gas flow rate; 150 to 180 mL min<sup>-1</sup> helium cell gas flow rate; 50 mL min<sup>-1</sup> to 90 mL min<sup>-1</sup> ion mobility gas flow rate; 50 V Trap voltage; 400 m s<sup>-1</sup> to 1000 m s<sup>-1</sup> IMS wave velocity; 15 V to 40 V IMS wave height. All IMS measurements were carried out using nitrogen as the mobility gas, at a pressure of 3.41 mbar. Data acquisition and processing were carried out using MassLynx (v4.1). The quantitative affinity measurements were carried out in positive ion mode using a Synapt G2S quadrupole-ion mobility separation-time-of-flight (Q-IMS-TOF) mass spectrometer (Waters UK Ltd., Manchester, UK). Details of the instrumental conditions used and data analysis are given as Supporting Information.

### Glycan array screening for binding of BabA

Binding of BabA to a mammalian glycan array was assessed by the Consortium for Functional Glycomics (CFG, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, USA) using their in-house glycan binding assay protocols and reagents. Binding of BabA to the printed surface of the CFG version 5.2 array, containing 609 synthetic and mammalian glycans, was performed in a 20 mM Tris-Cl (pH 7.4), 300 mM NaCl and 0.05% Tween-20 buffer. Bound BabA was detected with a fluorescein isothiocyanate labelled anti-c-Myc antibody.

### Results and discussion

A two-step approach was used to identify HMO ligands, present in the fractions, for the two lectins (Figure 1). First, each fraction was analyzed by ESI-IMS-MS/MS in order to identify, to the extent possible, the HMOs present. This was accomplished by comparing the MWs, IMS-ATs and CID fingerprints of ions detected from the fractions and the MWs of the most abundant oligosaccharides found in human milk<sup>13-15</sup> and IMS-ATs and CID fingerprints recently reported for a library of thirty-one purified HMOs.<sup>34</sup> In cases where appropriate HMO standards were not available, possible HMO structures were suggested based on the CID fragmentation data and the

1  
2  
3 structures known to be present in human milk. To our knowledge, the present work represents  
4 the first demonstration of using IMS-ATs and CID fingerprinting to identify HMOs in mixtures  
5 extracted from human milk. Following the characterization of the fractions, they were screened  
6 against the lectin using CaR-ESI-MS and ligands identified from a comparison of the MWs, IMS  
7 ATs and CID fingerprints of the released and free HMOs.

14  
15 **a. ESI-MS analysis of HMO fractions *Fr1* – *Fr4***

16 Shown in Figures 2 and S1-S5 (Supporting Information) are representative ESI mass spectra and  
17 IMS arrival time distributions (ATDs), acquired in negative ion mode, for aqueous solutions of  
18 each of the four fractions. Singly and doubly deprotonated ions corresponding to twelve HMO  
19 MWs (633.21 Da, 837.25 Da, 853.31 Da, 999.36 Da, 1056.39 Da, 1072.38 Da, 1202.30 Da,  
20 1218.44 Da, 1364.50 Da, 1510.32 Da, 1583.46 Da and 1729.64 Da) were identified in *Fr1*, six  
21 MWs (691.25 Da, 707.25 Da, 837.25 Da, 853.31 Da, 999.36 Da and 1218.44 Da) in *Fr2*, two in  
22 *Fr3* (488.17 Da and 707.25 Da), as well as lactose, and seven in *Fr4* (633.21 Da, 836.20 Da,  
23 998.34 Da, 1289.44 Da, 1509.54 Da, 1655.59 Da and 1800.63 Da). It should be noted that some  
24 of the HMO MWs were detected in multiple fractions. The monosaccharide compositions of the  
25 twenty-one different HMO MWs, which contain between three and ten monosaccharide units,  
26 were identified (Table 1). Fourteen of the MWs correspond to neutral HMOs (twelve of these are  
27 fucosylated), with the remaining seven corresponding to acidic HMOs (three are fucosylated).

45 The deprotonated ions (singly or doubly charged) associated with each HMO MW were  
46 then subjected to IMS analysis and CID fingerprinting and the results compared to those  
47 measured for **HMO1-HMO31**.<sup>34</sup> As an example, the IMS and CID data acquired for the HMOs  
48 in *Fr2* are shown in Figure 2; the corresponding results obtained for *Fr1*, *Fr3* and *Fr4* are shown  
49 in Figures S2-S5 (Supporting Information). Inspection of Figure 2 reveals that the IMS-ATDs

measured for deprotonated ions corresponding to HMO MWs of 691.25 Da (m/z 690.25), 837.25 Da (m/z 836.25) and 853.31 Da (m/z 852.31) exhibit single features, with ATs of 6.17 ms (Figure 2b), 12.32 ms (Figure 2d) and 12.43 ms (Figure 2e), respectively. For the MWs 707.25 Da (m/z 707.25), 999.36 Da (m/z 998.36) and 1218.44 Da (m/z 608.22) the IMS-ATDs consisted of two and three features, respectively, with ATs of 10.34 Da and 11.66 Da (for 707.25 Da (m/z 707.25)) and 15.18 ms, 15.29 ms and 16.28 ms (for 999.36 Da (m/z 998.36)), 6.16 ms and 6.71 ms (for 1218.44 Da (m/z 608.22)) (Figures 2c, 2f and 2a, respectively). The IMS-ATD measured for the 853.31 Da HMO (m/z 852.31) has a broad distribution (FWHM 1.2 ms) centred at 12.43 ms, consistent with the presence of multiple isomers (Figure 2e).<sup>34</sup>

Four of the measured MWs (691.25 Da, 707.25 Da, 999.36 Da and 853.31 Da) present in *Fr2* coincide with those of HMOs in the thirty-one component library (**HMO1-HMO31**). Comparison of the IMS-ATDs reveals that the ion corresponding to MW 691.25 Da (m/z 690.25), which has an AT of 6.17 ms, matches that of **HMO30** (Figure 2b). The two features (with ATs of 10.34 ms and 11.66 ms) observed for the ions corresponding to MW 707.25 Da (m/z 706.25) match the IMS-ATs measured for **HMO6** and **HMO7** (Figure 2c). The three partially resolved features (with ATs of 15.18 ms, 15.29 ms and 16.28 ms) measured for the ions with MW 999.36 Da (m/z 998.36) match those of **HMO18**, **HMO19** and **HMO20**, respectively (Figure 2f). Additionally, the CID mass spectrum acquired for deprotonated ions of MW 853.31 Da (m/z 853.31) revealed the presence of unique HMO fragments arising from five different HMOs, C<sub>2</sub> (m/z 325.12) from **HMO9**, <sup>0,4</sup>A<sub>2</sub>/Z<sub>3β</sub> (m/z 288.10) from **HMO10**, C<sub>2</sub>/Z<sub>3β</sub> (m/z 364.11) from **HMO11**, C<sub>2</sub>/Z<sub>3</sub> (m/z 202.07) from **HMO12** and <sup>0,2</sup>A<sub>2</sub>-H<sub>2</sub>O (m/z 263.10) from **HMO13** (Figure 2g).

Following the same approach, the other three fractions were analyzed and the HMOs identified are listed in Table 1. Together, the four fractions are found to contain at least thirty-five different HMOs, corresponding to twenty-one different MWs. The structures of twenty-five HMOs (corresponding to eleven different MWs) were established from the measured IMS-ATs and CID fingerprints and comparison with those of purified HMOs. Eighteen of these are neutral HMOs (of which fourteen are fucosylated) and seven are acidic HMOs. For the other MWs, only monosaccharide compositions could be determined. However, it was possible to suggest HMO structures based on previously identified HMOs having the same monosaccharide compositions.<sup>13,14</sup> In certain cases, it was possible to reduce the number of structures based on an analysis of the fragment ions produced by CID (Figures S6-S15, Supporting Information). For example, CID of deprotonated HMOs with MW 836.25 Da (Hex2HexNAcSia) produced fragment ions at  $m/z$  306.14,  $m/z$  470.14 and  $m/z$  493.15 (Figure S6, Supporting Information), which are indicative of  $\alpha$ 2 $\rightarrow$ 6 linked sialic acid,  $\alpha$ -Neu5Ac-(2 $\rightarrow$ 6)- $\beta$ -Gal and  $\alpha$ -Neu5Ac-(2 $\rightarrow$ 6)- $\beta$ -GlcNAc, respectively.<sup>39</sup> These data, taken together with the previously identified HMOs with Hex2HexNAcSia composition, suggest the presence of both  $\beta$ -GlcNAc-(1 $\rightarrow$ 3)-[ $\alpha$ -Neu5Ac-(2 $\rightarrow$ 6)]- $\beta$ -Gal-(1 $\rightarrow$ 4)- $\beta$ -Glc and  $\alpha$ -Neu5Ac-(2 $\rightarrow$ 6)- $\beta$ -GlcNAc-(1 $\rightarrow$ 3/6)- $\beta$ -Gal-(1 $\rightarrow$ 4)- $\beta$ -Glc.

### b. Screening HMO fractions against hGal-3C

Having established the HMO compositions of *Fr1-Fr4*, each fraction was screened against hGal-3C. Shown in Figure 3a is a representative ESI mass spectrum acquired in negative ion mode for aqueous ammonium acetate solutions (40 mM, pH 6.8) of hGal-3C (15  $\mu$ M),  $P_{ref}$  (5  $\mu$ M) and *Fr2* (0.05  $\mu$ g  $\mu$ L<sup>-1</sup>). Signal corresponding to hGal-3C bound to HMOs with five different MWs (691.25 Da ( $m/z$  690.29), 707.25 Da ( $m/z$  706.24), 837.25 Da ( $m/z$  836.20), 853.31 Da ( $m/z$  852.30) and 999.36 Da ( $m/z$  998.37)) was detected. The absence of signal corresponding to

1  
2  
3 HMO-bound  $P_{\text{ref}}$  ions indicates that non-specific HMO-hGal-3C binding during the ESI process  
4 was negligible.<sup>26</sup> From the MWs of the detected hGal-3C-HMO complexes it was possible to  
5 identify only one of the HMO ligands (**HMO30**, MW 691.25 Da); each of the other detected  
6 MWs could, in principle, correspond to multiple HMOs.  
7  
8  
9  
10

11 To identify the other HMO ligands, the (hGal-3C + HMO) complexes at the -7 charge  
12 state, the most abundant charge state detected, were isolated using the quadrupole mass filter (set  
13 to pass a range (~200 m/z) of ions), and subjected to collisional activation in the Trap region.  
14 The selected Trap voltage (40 V) allowed for the efficient release of the HMOs from hGal-3C  
15 without causing significant secondary fragmentation. Signal corresponding to deprotonated  
16 HMO ions (as well as chloride adducts) of the five different MWs were detected (Figure 3b).  
17 From comparison of the IMS-ATDs and CID fingerprints of the released HMO ions with  
18 available data for purified HMOs of the same MW, nine HMO ligands (**HMO6**, **HMO7**, **HMO9**,  
19 **HMO10**, **HMO11**, **HMO12**, **HMO13**, **HMO18** and **HMO30**) were positively identified (Figure  
20 3c-3h), in addition to the HMO with MW 837.25 Da.

1 Similar analysis of the CaR-ESI-MS data acquired for the other three fractions with hGal-  
2 3C was performed (Figures S16-S18, Supporting information). Taken together, the CaR-ESI-MS  
3 data obtained for the four fractions revealed HMO ligands corresponding to seventeen different  
4 MWs (Table 2). The structures of twenty-one HMO ligands (corresponding to eleven different  
5 MWs) were established from IMS-ATs and CID fingerprints. For the remaining six MWs only  
6 monosaccharide composition (and their corresponding putative structures) could be determined  
7 (Table 2). Notably, all of the twenty-one HMO ligands for which the structures were  
8 conclusively identified (**HMO1**, **HMO3**, **HMO6**, **HMO7**, **HMO9** - **HMO17**, **HMO18**,

1  
2  
3 **HMO21, HMO22, HMO25 - HMO27, HMO30 and HMO31**) were previously shown to bind  
4 to hGal-3C with measurable affinity.<sup>21</sup>  
5  
6

### 7 **c. Screening HMO fractions against BabA**

8  
9  
10 Having established that the CaR-ESI-MS assay can be applied to HMO fractions, the assay was  
11 used to screen *Fr1 - Fr4* against a truncated form of BabA, corresponding to the extracellular  
12 region of the adhesin. Shown in Figure 4a is a representative ESI mass spectrum acquired in  
13 negative ion mode for an aqueous ammonium acetate solution (40 mM, pH 6.8) of BabA (5  $\mu$ M)  
14 and *Fr2* (0.05  $\mu$ g  $\mu$ L<sup>-1</sup>). Signal corresponding to both free and HMO-bound BabA ions, at charge  
15 states -11 to -14, were detected. Unlike with hGal-3C, the individual (BabA + HMO) complex  
16 ions were not well resolved, making it impossible to determine the MWs of the bound HMOs.  
17 Collisional activation of the (BabA + HMO) complexes, at the -13 charge state, resulted in the  
18 appearance of ions corresponding to five different HMO MWs (Figure 4b). Based on the IMS-  
19 ATs and CID fingerprints of the released ions, eleven different HMO ligands were positively  
20 identified - **HMO6, HMO7, HMO9-HMO13, HMO18-HMO20 and HMO30** (Figures 4c-4h),  
21 plus the HMO with MW 837.25 Da. The other three fractions were screened in a similar fashion  
22 and the results are shown in Figures S19-S21 (Supporting Information).

36  
37  
38  
39

40 In total, CaR-ESI-MS screening identified HMO ligands of BabA at nine different MWs  
41 (Table 3). The specific structures of nineteen of these (corresponding to seven different MWs)  
42 were identified (Table 3). Thirteen of the HMOs are neutral (**HMO1, HMO2, HMO6, HMO7,**  
43 **HMO9, HMO10, HMO11, HMO12, HMO13, HMO18, HMO19, HMO20, HMO30**), with  
44 two of these being non-fucosylated (**HMO6 and HMO7**). Notably, BabA is also found to  
45 recognize the acidic HMOs (**HMO3, HMO4 and HMO14 - HMO17**). The broad specificity of  
46 BabA for HMOs, both neutral and acidic, is, at least in part, consistent with the findings of  
47  
48

1  
2  
3 previous studies on glycan binding. BabA was shown previously to bind to the blood group O  
4 determinants on type 1 core chains, i.e., Lewis b antigen ( $\alpha$ -L-Fuc-(1 $\rightarrow$ 2)- $\beta$ -D-Gal-(1 $\rightarrow$ 3)-[ $\alpha$ -L-  
5 Fuc-(1 $\rightarrow$ 4)]- $\beta$ -D-GlcNAc-) and the crystal structure of BabA with **HMO18**, which contains this  
6 motif ( $\alpha$ -L-Fuc-(1 $\rightarrow$ 2)- $\beta$ -D-Gal-(1 $\rightarrow$ 3)-[ $\alpha$ -L-Fuc-(1 $\rightarrow$ 4)]- $\beta$ -D-GlcNAc-(1 $\rightarrow$ 3)- $\beta$ -D-Gal(1 $\rightarrow$ 4)- $\beta$ -  
7 D-Glc) was reported.<sup>40</sup> BabA also recognizes the H type 1 determinant ( $\alpha$ -L-Fuc-(1 $\rightarrow$ 2)- $\beta$ -D-Gal-  
8 (1 $\rightarrow$ 3)- $\beta$ -D-GlcNAc-), which is found in **HMO9** ( $\alpha$ -L-Fuc(1 $\rightarrow$ 2)- $\beta$ -D-Gal(1 $\rightarrow$ 3)- $\beta$ -D-  
9 GlcNAc(1 $\rightarrow$ 3)- $\beta$ -D-Gal(1 $\rightarrow$ 4)- $\beta$ -D-Glc).<sup>35,36,40,41</sup> Results obtained by screening BabA against a  
10 mammalian glycan array (Consortium for Functional Glycomics, array version 5.2, Figure S22,  
11 Supporting Information) also suggest that the acidic HMOs **HMO3** and **HMO4** and the non-  
12 fucosylated HMOs **HMO6** and **HMO7** are BabA ligands.

60

The ability of BabA to bind to both fucosylated and non-fucosylated neutral, as well as acidic, HMOs is curious. The protein, which is mainly composed of  $\alpha$  helices, is known to possess a shallow binding site at the tip of a region called the ‘crown’, consisting of four antiparallel  $\beta$ -strands located on the head region. Analysis of the reported crystal structure of BabA (*H. pylori* strain J99; 4ZH7.pdb) with **HMO18** suggests that Fuc1 is critical for binding as it participates in a network of hydrogen bonds with C189, G191, N194 and T246. Gal5, GlcNAc3 and Fuc4 also participate in one or more intermolecular or water-mediated hydrogen bonds.<sup>40</sup> Based on this analysis, it is difficult to rationalize the binding of the HMOs that lack the critical elements of the Lewis b hexasaccharide structure, in particular the non-fucosylated and acidic HMOs, at the known binding site. This raises the question of whether BabA possesses an additional glycan binding site (or sites) that recognize HMOs. To test this possibility, ESI-MS binding measurements were performed on solutions of BabA with **HMO18** and either an acidic (**HMO3**) or non-fucosylated HMO (**HMO6**), in varying concentrations. Notably, the mass

1  
2  
3 spectra showed evidence of ternary complexes (BabA + **HMO18** + **HMO3**) (Figure S23) and  
4  
5 (BabA + **HMO18** + **HMO6**) (Figure S24, Supporting Information). These results indicate that  
6  
7 BabA possesses at least one additional glycan binding site, distinct from that occupied by  
8  
9 **HMO18**, which can recognize HMOs. However, follow-up studies are required to establish the  
10  
11 number and nature of the newly identified HMO binding site(s).  
12  
13

14  
15 The aforementioned binding data also suggest that the affinities of the **HMO3** and  
16  
17 **HMO6** for BabA are lower than that of **HMO18**. To establish this more conclusively, ESI-MS  
18  
19 affinity measurements were performed on solutions of BabA and individual HMOs (**HMO1**,  
20  
21 **HMO2**, **HMO3**, **HMO4**, **HMO6**, **HMO7** and **HMO9**, as well as **HMO18**). Representative ESI  
22  
23 mass spectra are shown in Figures S25 and S26 (Supporting Information). From an analysis of  
24  
25 the relative abundances of the free and HMO-bound BabA ions, the affinities of **HMO9** and  
26  
27 **HMO18**, which presumably bind predominantly at the previously identified binding site, were  
28  
29 measured to be  $\sim 10^4 \text{ M}^{-1}$ . This value agrees, within a factor of 3, with a value reported previously  
30  
31 for **HMO18**.<sup>40</sup> The affinities of the other HMOs tested are somewhat lower, between  $1 \times 10^3 \text{ M}^{-1}$   
32  
33 and  $4 \times 10^3 \text{ M}^{-1}$  (Table S2, Supporting Information).  
34

37

### 38 **Conclusions**

39  
40 This work describes the first application of CaR-ESI-MS for screening natural libraries of HMOs,  
41  
42 derived from pooled breast milk, against target proteins. A total of twenty-one different HMO  
43  
44 MWs were identified in the four fractions used in the present study. The structures of twenty-five  
45  
46 HMOs, corresponding to eleven different MWs, were identified based on their IMS-ATs and  
47  
48 CID fingerprints. To our knowledge, this is the first report describing the use of IMS-ATs and  
49  
50 CID fingerprinting for identifying HMOs in mixtures. For the other MWs, monosaccharide  
51  
52 composition and, in some cases, possible structures were established. Implementation of the  
53  
54 assay was demonstrated using hGal-3C, which served as a model HMO binding lectin. The assay  
55  
56  
57  
58  
59  
60

revealed HMO ligands corresponding to seventeen different MWs. From a comparison of IMS-ATs and CID fingerprints measured for the released HMO ligands and for a library of thirty-one pure HMOs, the structures of twenty-one HMO ligands were identified. Each of these glycans was previously shown to bind to hGal-3C. The presence of HMO ligands at six other MWs was also ascertained; however, the exact structures of these ligands could not be conclusively established. Application of the assay to BabA revealed nineteen specific HMO structures that are recognized by the protein and HMO ligands at two other MWs. Notably, it is found that BabA exhibits broad specificity for HMOs, and can bind to both neutral HMOs, including non-fucosylated ones, and acidic HMOs. The results of competitive binding experiments revealed that, at least, some HMOs can interact with BabA at a previously unknown binding site (or sites); however, the number and nature of the HMO binding site(s) were not established. Finally, the results of quantitative binding measurements performed on eight purified HMOs for BabA produced affinities that are in the  $10^3 \text{ M}^{-1}$  to  $10^4 \text{ M}^{-1}$  range.

- a. Possible structures based on CID results and identified HMOs reported in references 13 and 14.

**Table 2.** MW and monosaccharide composition (Hex  $\equiv$  Glc or Gal; HexNAc  $\equiv$  GlcNAc; Fuc  $\equiv$  fucose and Sia  $\equiv$  sialic acid) of HMO ligands of hGal-3C identified from *Fr1 – Fr4* using CaR-ESI-MS. The identity of specific HMO structures was based on a comparison of IMS-ATs and CID fingerprints of deprotonated ligand ions released from hGal-3C and those of **HMO1 – HMO31**.

- a. Possible structures based on CID results and identified HMOs reported in references 13 and 14.

**Table 3.** HMO ligands of BabA identified from *Fr1 – Fr4* using CaR-ESI-MS. The identity of specific HMO structures was based on a comparison of IMS-ATs and CID fingerprints of deprotonated ligand ions released from hGal-3C and those of **HMO1 – HMO31**.

- a. Possible structures based on CID results and identified HMOs reported in references 13 and 14.

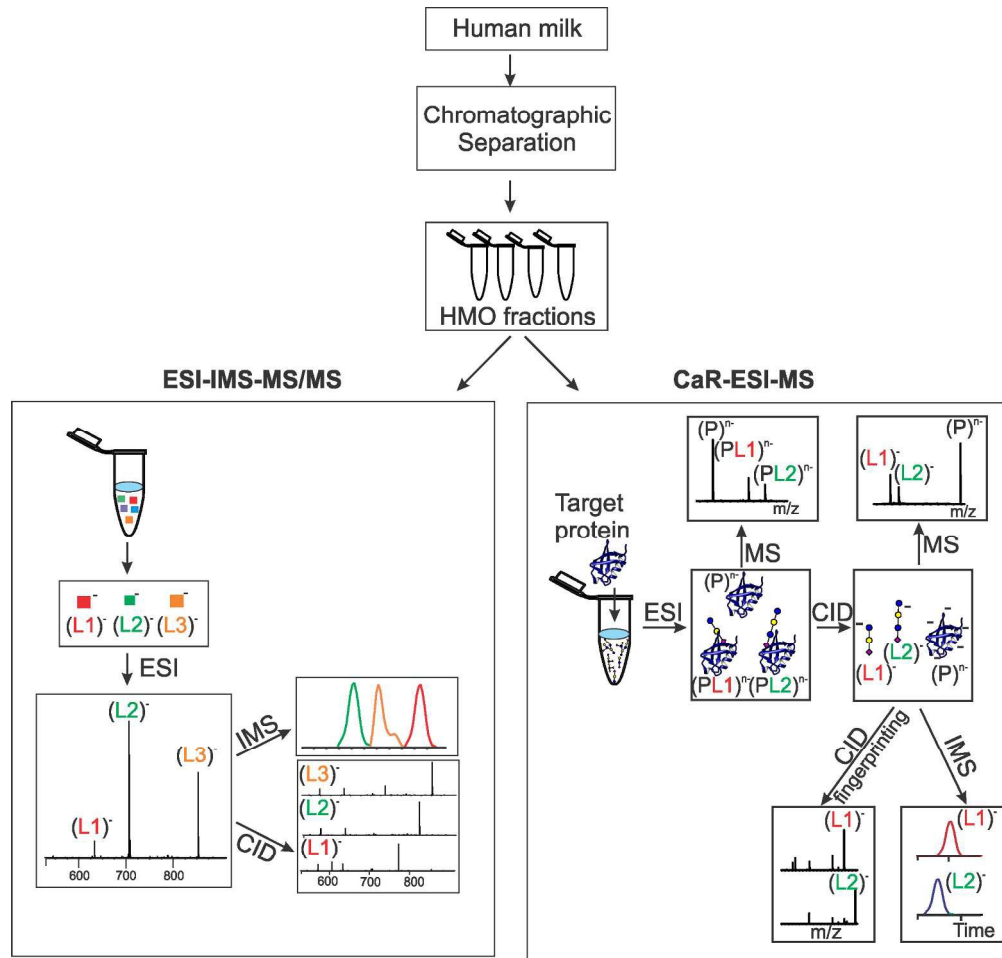

Figure 1. Overview of the two-step approach (ESI-IMS-MS/MS and CaR-ESI-MS) for screening HMO mixtures, extracted from human milk, against lectins.

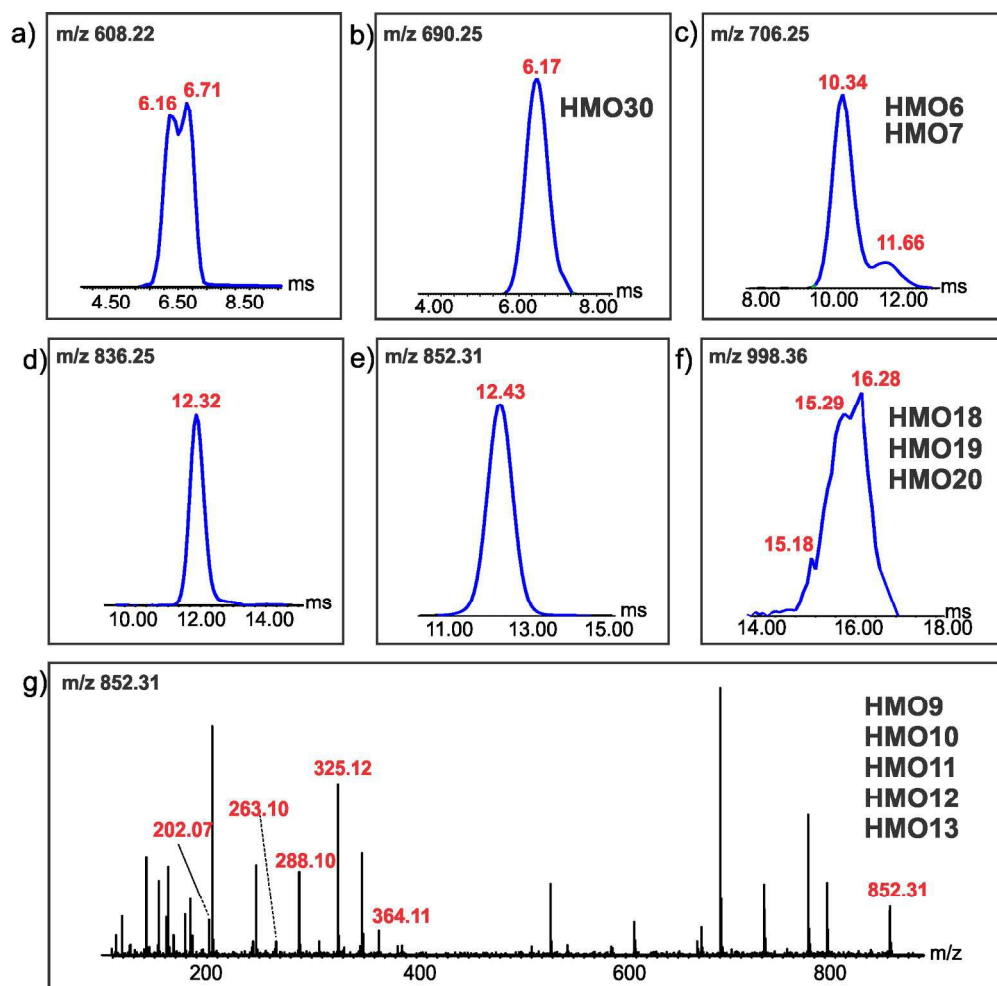

Figure 2. IMS-ATDs measured for the deprotonated HMO ions at (a) m/z 608.22; (b) m/z 690.25; (c) m/z 706.25; (d) m/z 836.25; (e) m/z 852.31 and (f) m/z 998.36 produced by ESI performed on an aqueous ammonium acetate solution (40 mM, pH 6.8) of Fr2 (0.05  $\mu\text{g } \mu\text{L}^{-1}$ ). (g) CID mass spectrum acquired in the Transfer region at 30 V for deprotonated HMO ions at m/z 852.31.

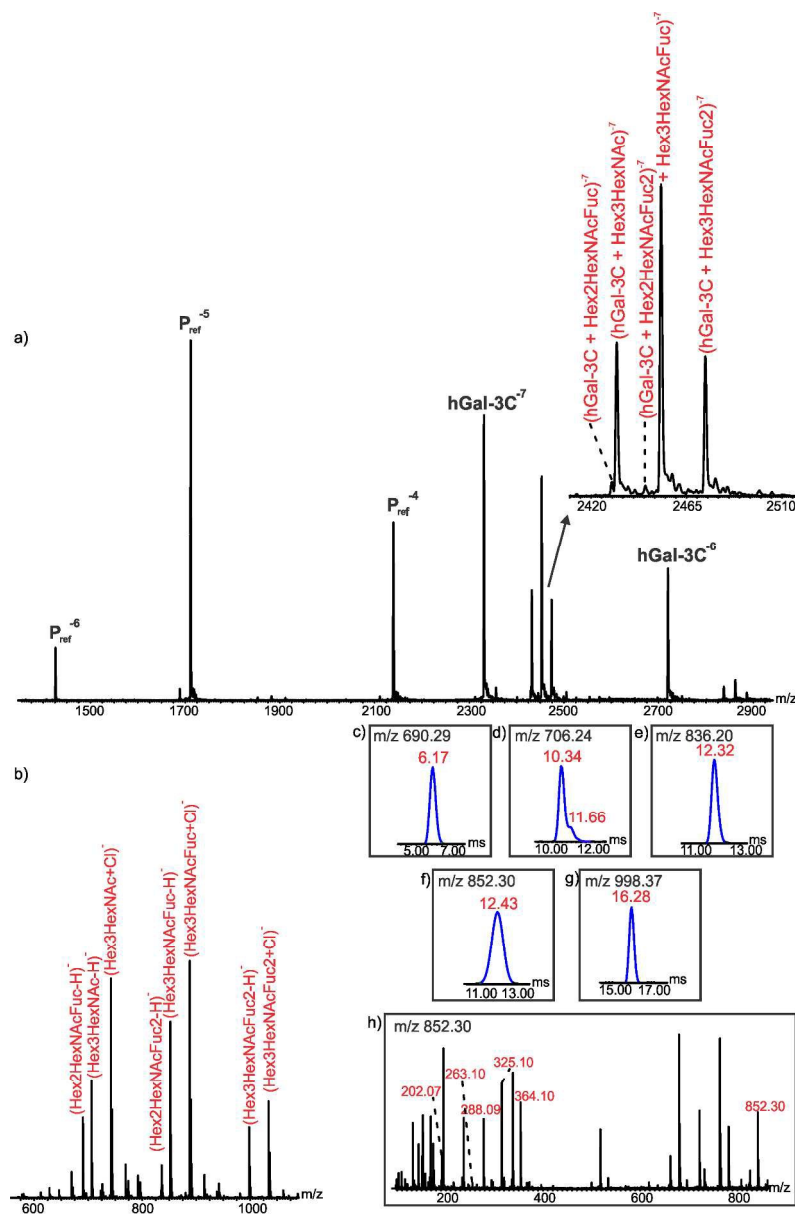

Figure 3. (a) Representative ESI mass spectra acquired in negative ion mode for 40 mM aqueous ammonium acetate solutions (pH 6.8) of  $P_{ref}$  ( $5 \mu M$ ),  $Fr2$  ( $0.05 \mu g \mu L^{-1}$ ) and  $hGal-3C$  ( $15 \mu M$ ), (b) CID mass spectrum acquired for all  $(hGal-3C + HMO)^{7-}$  ions at a Trap voltage of 40 V showing the released HMOs ligands; IMS-ATDs of (c)  $m/z$  690.29 (d)  $m/z$  706.24; (e)  $m/z$  836.20; (f)  $m/z$  852.30; (g)  $m/z$  998.37; (h) CID mass spectrum acquired for released HMO anions with IMS-AT of 12.43 ms using a Transfer voltage of 30 V.

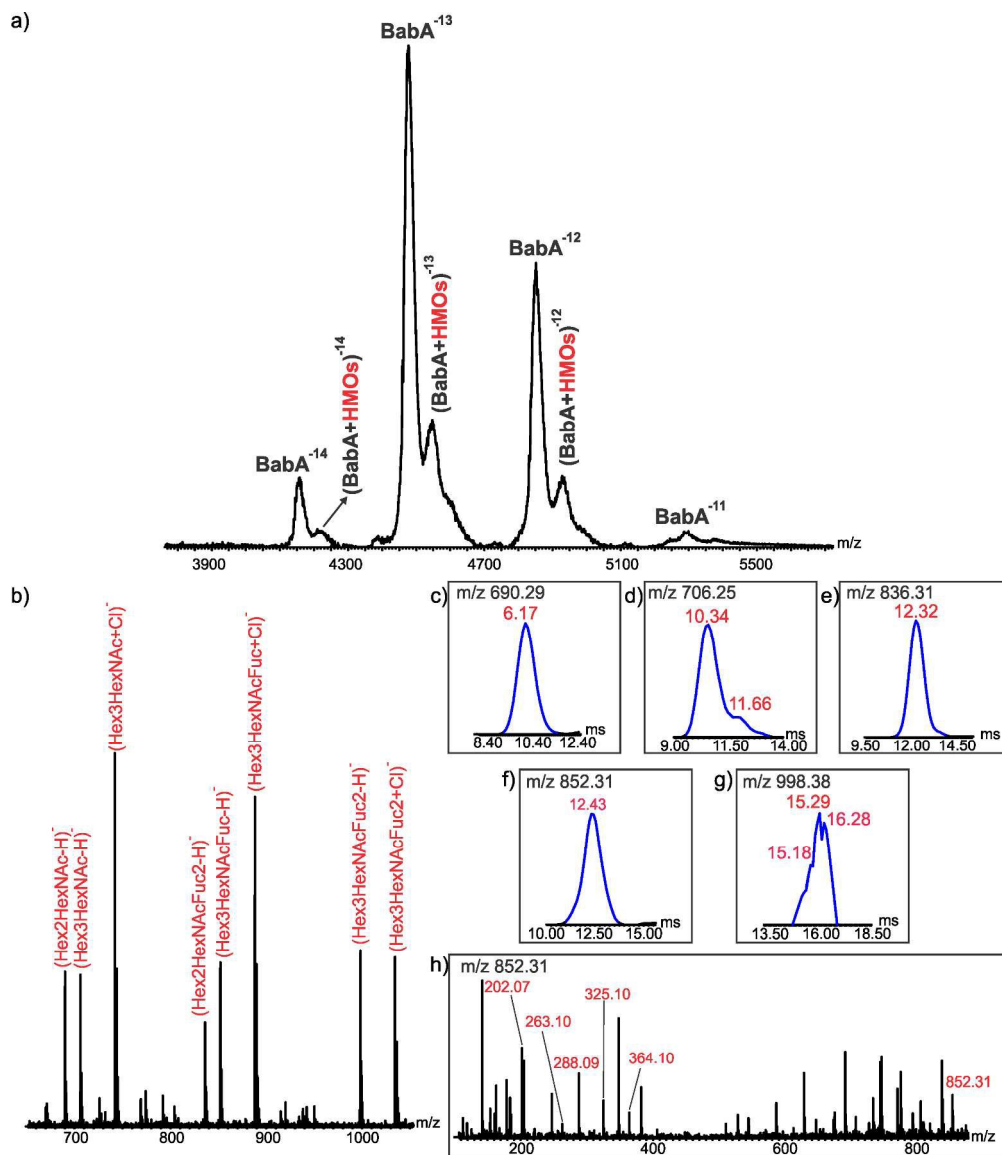

Figure 4. (a) Representative ESI mass spectra acquired in negative ion mode for 40 mM aqueous ammonium acetate solutions (pH 6.8) of Fr2 (0.05  $\mu\text{g } \mu\text{L}^{-1}$ ) and BabA (5  $\mu\text{M}$ ), (b) CID mass spectrum acquired for all (BabA + HMO)<sup>13-</sup> ions at a Trap voltage of 90 V showing the released HMOs ligands; IMS-ATDs of (c) m/z 690.29 (d) m/z 706.25; (e) m/z 836.31; (f) m/z 852.31; (g) m/z 998.38; (h) CID mass spectrum acquired for released HMO anions with IMS-AT of 12.43 ms using a Transfer voltage of 30 V.
