Abstract

Background

Melanoma has one of the fastest rising incidence rates of any cancer. It accounts for a small percentage of skin cancer cases but is responsible for the majority of skin cancer deaths. History-taking and visual inspection of a suspicious lesion by a clinician is usually the first in a series of 'tests' to diagnose skin cancer. Establishing the accuracy of visual inspection alone is critical to understating the potential contribution of additional tests to assist in the diagnosis of melanoma.

Objectives

To determine the diagnostic accuracy of visual inspection for the detection of cutaneous invasive melanoma and intraepidermal melanocytic variants in adults with limited prior testing and in those referred for further evaluation of a

suspicious lesion. Studies were separated according to whether the diagnosis was recorded face-to-face (in-person) or based on remote (image-based) assessment.

Search methods

We undertook a comprehensive search of the following databases from inception up to August 2016: Cochrane Central Register of Controlled Trials; ; CINAHL; CPCI; Zetoc; Science Citation Index; US National Institutes of Health Ongoing Trials Register; NIHR Clinical Research Network Portfolio Database; and the World Health Organization International Clinical Trials Registry Platform. We studied reference lists and published systematic review articles.

Selection criteria

Test accuracy studies of any design that evaluated visual inspection in adults with lesions suspicious for melanoma, compared with a reference standard of, either histological confirmation or clinical follow-up. Studies reporting data for 'clinical diagnosis' where dermoscopy may or may not have been used were excluded.

Data collection and analysis

Two review authors independently extracted all data using a standardised data extraction and quality assessment form (based on QUADAS-2). We contacted authors of included studies where information related to the target condition or diagnostic threshold were missing. We estimated summary sensitivities and specificities per algorithm and threshold using the bivariate hierarchical model. We investigated the impact of: in-person test interpretation; use of a purposely developed algorithm to assist diagnosis; and observer expertise.

Main results

Forty-nine publications reporting on a total of 51 study cohorts with 34,351 lesions (including 2499 cases) were included, providing 134 datasets for visual inspection. Across almost all study quality domains, insufficient information was provided in the majority of study reports to allow the risk of bias to be judged, while concerns regarding applicability of study findings were scored as 'High' in three of four domains assessed. Selective participant recruitment, lack of detail regarding the threshold for deciding on a positive test result, and lack of detail on observer expertise were particularly problematic.

Attempts to analyse studies by degree of prior testing were hampered by a lack of relevant information and by the restricted inclusion of lesions selected for biopsy or excision. Accuracy was generally much higher for in-person diagnosis compared to image-based evaluations (relative diagnostic odds ratio of 8.54, 95% CI 2.89, 25.3, $P < 0.001$). Meta-analysis of in-person evaluations that could be clearly placed on the clinical pathway showed a general trade-off between sensitivity and specificity, with the highest sensitivity (92.4%, 95% CI 26.2, 99.8%) and lowest specificity (79.7%, 95% CI 73.7, 84.7%) observed in participants with limited prior testing ($n = 3$ datasets). Summary sensitivities were lower for those referred for specialist assessment but with much higher specificities (e.g. sensitivity 76.7% (95% CI 61.7, 87.1%) and specificity 95.7% (95% CI 89.7, 98.3%) for lesions selected for excision, $n = 8$ datasets). These differences may be related to differences in the spectrum of included lesions, differences in the definition of a positive test result, or to variations in observer expertise. We did not find clear evidence that accuracy is improved by the use of any algorithm to assist diagnosis in all settings. Attempts to examine the effect of observer expertise in melanoma diagnosis were hindered due to poor reporting.

Authors' conclusions

Visual inspection is a fundamental component of the assessment of a suspicious skin lesion; however, the evidence suggests that melanomas will be missed if visual inspection is used on its own. The evidence to support its accuracy in the range of settings in which it is used is flawed and very poorly reported. Although published algorithms do not appear to improve accuracy, there is insufficient evidence to suggest that the 'no algorithm' approach should be preferred in all settings. Despite the volume of research evaluating visual inspection, further prospective evaluation of the potential added value of using established algorithms according to the prior testing or diagnostic difficulty of lesions may be warranted.

Plain language summary

What is the diagnostic accuracy of visual inspection of skin lesions with the naked eye for diagnosis of melanoma in adults?

What is the aim of the review?

Melanoma is one of the most dangerous forms of skin cancer. The aim of this Cochrane Review was to find out the accuracy of visual inspection of suspicious skin lesions with the naked eye to diagnose melanoma. The Review also investigated whether diagnostic accuracy using visual inspection of suspicious skin lesions on a patient in-person differed to diagnostic accuracy of visual inspection of images of suspicious skin lesions. Researchers in Cochrane included 19 studies to answer this question.

Why is the diagnostic accuracy of visual examination of skin lesions suspected to be melanomas important?

Not recognising a melanoma when it is present (a false negative test result) delays surgery to remove it, risking cancer spreading to other organs in the body and possibly death. Diagnosing a skin lesion as a melanoma when it is not (a false positive result) may result in unnecessary surgery, further investigations, and patient anxiety. Visual inspection of suspicious skin lesions by a clinician using the naked eye is usually the first of a series of 'tests' to diagnose melanoma. Knowing the diagnostic accuracy of visual inspection alone is important to decide whether additional tests are needed to improve accuracy to an acceptable level.

What was studied in the review?

Researchers sought to find out the diagnostic accuracy of visual inspection of suspicious skin lesions on a patient in-person and the diagnostic accuracy of visual inspection of images of suspicious skin lesions. Researchers also sought to find out whether diagnostic accuracy was improved by use of a visual inspection checklist or by an increase in level of clinical expertise; they considered the diagnostic accuracy of the first visual inspection of a lesion, for example, by a GP, and of lesions which had been referred for further evaluation, for example, by a dermatologist.

What are the main results of the review?

Only 19 studies (17 in-person studies and 2 image-based studies) were clear whether the test was the first visual inspection of a lesion or was a visual inspection following referral (for example, when patients are referred by a general practitioner to skin specialists for visual inspection).

First visual inspection in-person (3 studies)

The results of 3 studies of 1339 suspicious skin lesions suggest that in a group of 1000 lesions, of which 90 (9%) actually are melanoma:

- An estimated 268 will have a visual inspection result indicating melanoma is present. Of these, 185 will not be melanoma and will result in an unnecessary biopsy (false positive results).

- An estimated 732 will have a visual inspection result indicating that melanoma is not present. Of these, 7 will actually have melanoma and would not be sent for biopsy (false negative results).

Two further studies restricted to 4228 suspicious skin lesions that were all selected to be excised found similar results.

Visual inspection in-person after referral, all lesions selected to be excised (8 studies)

The results of eight studies of 5331 suspicious skin lesions suggest that in a group of 1000 lesions, of which 90 (9%) actually are melanoma:

- An estimated 108 will have a visual inspection result indicating melanoma is present, and of these, 39 will not be melanoma and will result in an unnecessary biopsy (false positive results).

- Of the 892 lesions with a visual inspection result indicating that melanoma is not present, 21 will actually be melanoma and would not be sent for biopsy (false negative results).

Overall, the number of false positive results (diagnosing a skin lesion as a melanoma when it is not) was observed to be higher and the number of false negative results (not recognising a melanoma when it is present) lower for first visual inspections of suspicious skin lesions compared to visual inspection following referral.

Visual inspection of images of suspicious skin lesions (2 studies)

Accuracy was much lower for visual inspection of images of lesions compared to visual inspection in-person.

Value of visual inspection checklists

There was no evidence that use of a visual inspection checklist or the level of clinical expertise changed diagnostic accuracy.

How reliable are the results of the studies of this review?

In the majority of included studies, the diagnosis of melanoma was made by lesion biopsy and the absence of melanoma was confirmed by biopsy or by follow up over time to make sure the skin lesion remained negative for melanoma*. Biopsy or follow-up are likely to have been reliable methods for deciding whether patients really had melanoma. In a few studies, the absence of melanoma was made by expert diagnosis, which is less likely to have been a reliable method for deciding whether patients really had melanoma. There was lots of variation in the results of the studies in this review. Poor reporting of study conduct made assessment of the reliability of studies difficult. Selective inclusion of particular types of skin lesion, lack of detail about how the diagnosis of melanoma was made, and lack of detail on the expertise of the doctor doing the visual inspection were particularly problematic.

Who do the results of this review apply to?

Thirteen studies were undertaken in Europe (68%), with the remainder undertaken in Asia (n = 1), Oceania (n = 4), North America (n = 1). Mean age ranged from 30 to 73.6 years (reported in 10 studies). The percentage of individuals with melanoma ranged between 4% and 20% in first visualised lesions and between 1% and 50% in studies of referred lesions. In the majority of studies, the lesions were unlikely to be representative of the range of those seen in practice, for example, only including skin lesions of a certain size or with a specific appearance. In addition, variation in the expertise of clinicians performing visual inspection and in the definition used to decide whether or not melanoma was present across studies makes it unclear as to how visual inspection should be carried out and by whom in order to achieve the accuracy observed in studies.

What are the implications of this review?

Error rates from visual inspection are too high for it to be relied upon alone. Although not evaluated in this review, other technologies need to be used to ensure accurate diagnosis of skin cancer. There is considerable variation and uncertainty about the diagnostic accuracy of visual inspection alone for the diagnosis of melanoma. There is no evidence to suggest that visual inspection checklists reliably improve the diagnostic accuracy of visual inspection, so recommendations cannot be made about when they should be used. Despite the existence of numerous research studies, further, well-reported studies assessing the diagnostic accuracy of visual inspection with and without visual inspection checklists and by clinicians with

different levels of expertise are needed.

How up-to-date is this review?

The review authors searched for and used studies published up to August 2016.

*In these studies, biopsy, clinical follow up, or specialist clinician diagnosis were the reference standards.

Background

This review is one of a series of Cochrane Diagnostic Test Accuracy (DTA) reviews on the diagnosis and staging of melanoma and keratinocyte skin cancers conducted for the National Institute for Health Research (NIHR) Cochrane Systematic Reviews Programme. [Appendix 1](#) shows the content and structure of the programme. [Appendix 2](#) provides a glossary of terms used, and a table of acronyms used is provided in [Appendix 3](#).

Target condition being diagnosed

Melanoma is one of the most aggressive forms of skin cancer, with the potential to metastasise to other parts of the body via the lymphatic system and blood stream. It accounts for a small percentage of skin cancer cases but is responsible for up to 75% of skin cancer deaths ([Boring 1994](#); [Cancer Research UK 2017](#)).

Melanoma arises from uncontrolled proliferation of melanocytes - the epidermal cells that produce pigment or melanin. It most commonly arises in the skin but can occur in any organ that contains melanocytes, including mucosal surfaces, the back of the eye, and lining around the spinal cord and brain. Cutaneous melanoma refers to a skin lesion with malignant melanocytes present in the dermis, and includes superficial spreading, nodular, acral lentiginous, and lentigo maligna melanoma variants (see [Figure 1](#)). Melanoma in situ refers to malignant melanocytes that are contained within the epidermis and have not yet invaded the dermis, but are at risk of progression to melanoma if left untreated. Lentigo maligna, a subtype of melanoma-in-situ in chronically sun-damaged skin, denotes another form of proliferation of abnormal melanocytes. Lentigo maligna can progress to invasive melanoma if its growth breaches the dermo-epidermal junction during a vertical growth phase (when it becomes known as 'lentigo maligna melanoma'); however, its rate of malignant transformation is both lower and slower than for melanoma in situ ([Kasprzak 2015](#)). Melanoma in situ and lentigo maligna are both atypical intraepidermal melanocytic variants.

The incidence of melanoma rose to over 200,000 newly diagnosed cases worldwide in 2012 ([Erdmann 2013](#); [Ferlay 2015](#)), with an estimated 55,000 deaths ([Ferlay 2015](#)). In the UK, melanoma has one of the fastest rising incidence rates of any cancer and has the biggest projected increase in incidence between 2007 and 2030 ([Mistry 2011](#)). In the decade leading up to 2013, age standardised incidence increased by 46%, with 14,500 new cases in 2013 and 2,459 deaths in 2014 (<http://www.cancerresearchuk.org/health-professional/cancer-statistics/statistics-by-cancer-type/skin-cancer/incidence>). While overall incidence rates are higher in women than in men, the rate of incidence in the latter is increasing faster than in women ([Arnold 2014](#)).

The rising incidence in melanoma is thought to be primarily related to an increase in recreational sun exposure and tanning bed use and an increasingly ageing population with higher lifetime ultraviolet (UV) exposure, in conjunction with possible earlier detection ([Linos 2009](#); [Belbasis 2016](#)). Putative risk factors are reviewed in detail elsewhere ([Belbasis 2016](#)), but can be broadly divided into host or environmental factors. Host factors include fair skin and light hair or eye colour; older age ([Geller 2002](#)); male sex ([Geller 2002](#)); previous skin cancer ([Tucker 1985](#)); predisposing skin lesions, e.g. high melanocytic naevus counts ([Gandini 2005](#)), clinically atypical naevi ([Gandini 2005](#)), or large congenital naevi ([Swerdlow 1995](#)); genetically inherited skin disorders e.g. xeroderma pigmentosum ([Lehmann 2011](#)); and a family history of melanoma ([Gandini 2005](#)). Environmental factors include recreational, occupational, and work-related exposure to sunlight (both cumulative and episodic burning) ([Gandini 2005](#); [Armstrong 2017](#)); artificial tanning ([Boniol 2012](#)); and immunosuppression, e.g. in organ transplant recipients or human immunodeficiency virus (HIV)-positive individuals ([DePry 2011](#)). Lower socioeconomic class may be associated with delayed presentation and thus more advanced disease at diagnosis ([Reyes-Ortiz 2006](#)).

A database of over 40,000 US patients from 1998 onwards which assisted the development of the eighth American Joint Committee on Cancer (AJCC) Staging System indicated a five-year survival of 99% for stage IA melanoma (melanoma ≤ 1 mm thick without ulceration, mitosis or involvement of the lymph nodes), dropping to anything between 32% and 93% in stage III disease (melanoma of any thickness with metastasis to the lymph nodes) depending on tumour thickness, the presence of ulceration and number of involved nodes ([Gershenwald 2017](#)). Before the advent of targeted and immuno-therapies, stage IV melanoma (melanoma disseminated to distant sites / visceral organs) was associated with median survival of six to nine months, one year survival rate of 25%, and three year survival of 15% ([Balch 2009](#); [Korn 2008](#)).

Between 1975 and 2010, five year relative survival for melanoma (i.e. not including deaths from other causes) in the US increased from 80% to 94%, with survival for localised, regional, and distant disease estimated at 99%, 70%, and 18%, respectively in 2010 ([Cho 2014](#)). Overall, mortality rates however showed little change, at 2.1 per 100,000 deaths in 1975 and 2.7 per 100,000 in 2010 ([Cho 2014](#)). Increasing incidence in localised disease over the same period (from 5.7 to 21 per 100,000) suggests that much of the observed improvement in survival may be due to earlier detection and heightened vigilance ([Cho 2014](#)). New targeted therapies for stage IV melanoma (e.g. BRAF inhibitors) have improved survival and immunotherapies are evolving such that long term survival is being documented ([Pasquali 2018](#)). No new data regarding the survival prospects for patients with stage IV disease were analysed for the AJCC 8 staging guidelines due to lack of contemporary data ([Gershenwald 2017](#)).

Treatment of melanoma

For primary melanoma, the mainstay of definitive treatment is early detection and excision of the lesion, to remove both the tumour and any malignant cells that might have spread into the surrounding skin ([Garbe 2016](#); [Marsden 2010](#); [NICE 2015](#); [SIGN 2017](#); [Sladden 2009](#)). Recommended surgical margins vary according to tumour thickness ([Garbe 2016](#)) and stage of disease at presentation ([NICE 2015](#)).

Index test(s)

For the purposes of our series of reviews, each component of the diagnostic process, including visual inspection or clinical examination, is considered a diagnostic or index 'test', the accuracy of which can be established in comparison with a reference standard of diagnosis, either alone or in combination with other available technologies that may assist the diagnostic process.

Clinical history taking to identify risk factors and visual inspection of the lesion, surrounding skin and comparison with other lesions on the rest of the body is fundamental to the diagnosis of skin cancer. The strongest common phenotypic risk factor is the presence of atypical naevi; typically the presence of over a hundred moles or naevi of abnormal appearance that may pose diagnostic challenges ([Goodson 2010](#); [Rademaker 2010](#); [Salerni 2012](#)). In the UK, clinical examination is typically done at two decision points – first in the general practice (GP) surgery where a decision is made to refer or not to refer, and then a second time by a dermatologist or other secondary care clinician where a decision is made to biopsy or not. Specialist advice can also be sought using teledermatology, where lesion images are forwarded with variable clinical information (such as age, gender, and location of lesion) to specialist clinics or to commercial organisations for interpretation. The accuracy of these diagnostic encounters (defined as the proportion of 'correct' diagnoses, i.e. true positive plus true negative diagnoses out of the total number of diagnoses) is known to vary according to qualifications and experience ([Westerhoff 2000](#); [Morton 1998](#)); the accuracy of 'image-based' as opposed to face-to-face diagnosis is less clear.

Research into the cognitive processes involved in dermatological diagnoses suggests that two main strategies are employed simultaneously and iteratively ([Elstein 2002](#); [Norman 1989](#); [Norman 2009](#)). Non-analytical pattern recognition formulates an initial hypothesis; identification is made implicitly, without conscious thought or reference to specific rules and hidden from the conscious view of the diagnostician ([Norman 2009](#)). Analytical pattern recognition using more explicit rules based on conscious analytical reasoning is then employed to test the initial hypothesis. Analytical pattern recognition has been described as the "careful and systematic gathering of data and weighing the elicited information against mental rules" ([Norman 2009](#)). The balance between non-analytical and analytical reasoning varies between clinicians, according to factors such as experience and familiarity with the diagnostic question.

Various attempts have been made to formalise the "mental rules" involved in analytical pattern recognition for melanoma, ranging from setting out criteria that should be considered (e.g. 'pattern analysis'; [Sober 1979](#); [Friedman 1985](#)) to formal scoring systems with explicit numerical thresholds ([MacKie 1985](#); [MacKie 1990](#)). The most commonly used algorithms are described in detail in [Appendix 4](#).

The ABCD (asymmetry, border irregularity, colour variegation, diameter > 6 mm) algorithm of clinical warning signs was developed in 1985 to help distinguish melanoma from a benign naevus ([Friedman 1985](#)), and then extended to include an E for 'enlargement' criterion ([Thomas 1998](#)). As a result of its simplicity, ABCD(E) is now widely advocated for use by non-experts or lay persons ([American Academy of Dermatology 2015](#)). The approach has been criticised for its inability to capture nodular and amelanotic melanomas, which account for a relatively small proportion (~15% to 20%) of incident melanomas but a large proportion (~50%) of melanoma-related deaths ([Moreau 2013](#); [Shaikh 2012](#)). In addition, up to a third of melanomas may be < 6 mm in diameter ([Maley 2014](#)), a proportion which is likely to increase due to improved skin surveillance. The validity of ABCD(E) as a useful tool for the lay public has also been called into question ([Girardi 2006](#), [Liu 2005](#), [Aldridge 2011](#)). Subsequent modifications have been suggested, including altering the meaning of the ABCD acronym for use in paediatric populations ([Cordoro 2013](#)); changing 'D' to 'dark' ([Goldsmith 2014](#)); or changing the acronym altogether (e.g. CCC for colour, contour, and change ([Moynihan 1994](#)); or "Do UC" the melanoma for different, uneven, changing ([Yagerman 2014](#))). To date, the latter three have not been evaluated in populations with lesions suggestive for melanoma.

The seven-point checklist assessing change in size, shape, colour, inflammation, crusting or bleeding, sensory change, or diameter ≥ 7 mm was developed by UK researchers as a guide to help non-dermatologists detect possible melanoma ([MacKie 1985](#); [MacKie 1990](#)). The revised weighted version ([MacKie 1990](#)) is currently recommended for general practitioner (GP) use in the evaluation of pigmented lesions ([NICE 2015](#)). A primary care based evaluation found moderately good performance for the identification of clinically significant lesions (including malignant and premalignant lesions as disease positive) in primary care (sensitivity and specificity for the presence of ≥ 3 features were 62.7% and 65.0%, respectively), with higher sensitivity for the detection of melanoma (80.6%) at the expense of low specificity (61.7%) ([Walter 2013](#)).

Unlike most formalised rules, the 'ugly duckling' sign is based on differential pattern recognition where abnormal lesion identification is achieved by noticing the odd one out, i.e. a melanoma will be the pigmented lesion that does not match the rest of a person's naevi, for example a very dark or pale/pink lesion that is different in colour compared to the rest of the pigmented naevi ([Grob 1998](#)). Although ugly duckling is inherently a form of subjective pattern recognition, sensitivity has been reported to be 100% for pigmented-lesion experts and 85% for non-clinicians ([Scope 2008](#)). The assumption that an individual has a "normal" naevus phenotype is debatable, however. Many individuals have multiple 'atypical' pigmented lesions which, although very similar morphologically, allow malignancy to easily

disguise itself amidst an abnormal complex of pigmented lesions (also referred to as 'The Little Red Riding Hood' phenomenon) ([Mascaro 1998](#)).

Clinical Pathway

The diagnosis of melanoma can take place in primary, secondary, and tertiary care settings by both generalist and specialist healthcare providers. In the UK, people with concerns about a new or changing lesion will usually present first to their general practitioner or less commonly directly to a specialist in secondary care, which could include a dermatologist, plastic surgeon, general surgeon or other specialist surgeon (such as an ear, nose, and throat (ENT) specialist or maxillofacial surgeon), or ophthalmologist ([Figure 2](#)). Current UK guidelines recommend that all suspicious pigmented lesions presenting in primary care should be assessed by taking a clinical history and visual inspection using the seven-point checklist ([MacKie 1990](#)); lesions suspected to be melanoma should be referred urgently for appropriate specialist assessment within two weeks ([Chao 2013](#); [Marsden 2010](#); [NICE 2015c](#); [SIGN 2017](#)).

Teledermatology consultations can aid more appropriate triage of lesions into urgent referral; non-urgent secondary care referral (e.g. for suspected basal cell carcinoma); or where available, referral to an intermediate care setting, e.g. clinics run by GPs with a special interest in dermatology. The distinction between setting and examiner qualifications and experience is important as specialist clinicians might work in primary care settings (for example, in the UK, general practitioners (GPs) with a special interest in dermatology and skin surgery who have undergone appropriate training), and generalists might practice in secondary care settings (for example, plastic surgeons who do not specialise in skin cancer). The level of skill and experience in skin cancer diagnosis will vary for both generalist and specialist care providers and will also impact on test accuracy.

The specialist clinician will also use history-taking and visual inspection of the lesion (in comparison with other lesions on the skin), usually in conjunction with dermoscopic examination, to inform a clinical decision. If melanoma is suspected, then urgent excision biopsy is recommended; for suspected cutaneous squamous cell carcinoma (cSCC) urgent excision with predetermined surgical margins. Other lesions such as basal cell carcinoma (BCC) or pre-malignant lesions such as lentigo maligna may also be referred for a diagnostic biopsy, followed by appropriate treatment or further surveillance or reassurance and discharge.

Prior test(s)

Although smartphone applications and community-based teledermatology services can increasingly be directly accessed by people who have concerns about a skin lesion ([Chuchu 2018](#)), visual inspection of a suspicious lesion by a clinician is usually the first in a series of tests to diagnose skin cancer. In the UK first visual inspection of a suspicious lesion usually takes place in primary care; however, in some countries, people with suspicious lesions can present directly to a secondary care setting. Considering the degree of prior testing that study participants have undergone is key to interpretation of resulting test accuracy indices, which are known to vary according to the spectrum or case-mix of included participants ([Lachs 1992](#); [Moons 1997](#); [Leefflang 2013](#); [Usher-Smith 2016](#)). Studies of people with suspicious lesions at the initial clinical presentation stage ('test naïve') are likely to have a wider range of differential diagnoses and include a higher proportion of people with benign diagnoses compared with studies of participants who have been referred for a specialist opinion on the basis of visual inspection (with or without dermoscopy) by a generalist practitioner. Furthermore, studies in more specialist settings may focus on equivocal or difficult to diagnose lesions rather than lesions with a more general level of clinical suspicion. A simple categorisation of studies according to primary, secondary, or specialist setting may not always adequately reflect differences in spectrum.

Role of index test(s)

Visual inspection and history-taking are key to diagnosing skin cancer and are always undertaken as part of a clinical examination regardless of examiner experience and whatever additional technologies are available. For the generalist practitioner, the key is to minimise the proportion of people who are referred unnecessarily and identify those lesions that require urgent referral. For the specialist, the aim is not only to identify those in need of urgent excision due to invasive cancer, but also to identify high risk lesions with considerable potential to progress to invasive disease, such as those with severe dysplasia or *in situ* disease e.g. lentigo maligna, for example. Given differences in setting, prior testing, observer qualifications, experience and training, the anticipated performance in terms of accuracy is likely to vary.

When diagnosing potentially life-threatening conditions such as melanoma, the consequences of falsely reassuring a person that they do not have skin cancer can be serious and potentially fatal, as the resulting delay to diagnosis means that the window for successful early treatment may be missed. To minimise these false-negative diagnoses, a good diagnostic test will demonstrate high sensitivity and a high negative predictive value (NPV), where very few of those with a negative test result will actually have a melanoma. Giving falsely positive test results (meaning the test has poor specificity and a high false-positive rate) resulting in the removal of lesions that turn out to be benign is arguably less of an error than missing a potentially fatal melanoma, but is not cost free. False-positive diagnoses not only cause unnecessary scarring from the biopsy or excision procedure, but also increase patient anxiety whilst they await the definite histology results and increase healthcare costs as the number needed to remove to yield one melanoma diagnosis increases.

Alternative test(s)

A number of other tests have been reviewed as part of our series of Cochrane DTA reviews on the diagnosis of melanoma. In particular, dermoscopy has become an essential tool for the specialist clinician and is increasingly being taken up in primary care settings. Dermoscopy (also referred to as dermatoscopy or epiluminescence microscopy or ELM) uses a hand-held microscope and incident light (with or without oil immersion) to reveal subsurface images of the

skin at increased magnification of x 10 to x 100 ([Kittler 2011](#)). Used alongside clinical examination, dermoscopy has been shown in some studies to increase the sensitivity of clinical diagnosis of melanoma from around 60% to as much as 90% ([Kittler 1999](#); [Carli 2002](#); [Bono 2006](#); [Stanganelli 2000](#)) with much smaller effects in others ([Benelli 1999](#); [Bono 2002](#)). The accuracy of dermoscopy depends on the experience of the examiner ([Kittler 2011](#)), with accuracy when used by untrained or less experienced examiners potentially no better than clinical inspection alone ([Binder 1997](#); [Kittler 2002](#)).

Pattern analysis ([Steiner 1987](#); [Pehamberger 1993](#)) is thought to be the most specific and reliable technique to aid dermoscopy interpretation when used by specialists ([Maley 2014](#)); however, dermoscopic histological correlations have been established and diagnostic algorithms developed based on colour, aspect, pigmentation pattern, and skin vessels (e.g. the ABCD rule for dermoscopy ([Nachbar 1994](#); [Stolz 1994](#)), the Menzies ([Menzies 1996](#)) and the seven-point dermoscopy checklist ([Annessi 2007](#); [Argenziano 1998](#); [Argenziano 2001](#); [Gereli 2010](#); amongst others). Dermoscopy used in addition to visual inspection (in-person evaluations) or used alone (dermoscopic image interpretation remotely from the patient concerned) are the subject of a separate systematic review ([Dinnes 2018](#)).

A number of other tests which may have a role for the diagnosis of melanoma in a specialist setting have been reviewed as part of our series of systematic reviews, including teledermatology, mobile phone applications, reflectance confocal microscopy, optical coherence tomography, computer-aided diagnosis or artificial intelligence-based techniques, and high frequency ultrasound ([Dinnes 2015](#)). Evidence permitting, the accuracy of available tests will be compared in an overview review, exploiting within-study comparisons of tests and allowing the analysis and comparison of commonly used diagnostic strategies where tests may be used singly or in combination.

We also considered and excluded a number of tests from review including tests used in the context of monitoring people, such as total body photography of those with large numbers of typical or atypical naevi, and finally histopathological confirmation following lesion excision. The latter is the established reference standard for melanoma diagnosis and will be one of the standards against which the index tests are evaluated in these reviews.

Rationale

Our series of reviews of diagnostic tests used to assist clinical diagnosis in either clinical practice or in a research setting aims to identify the most accurate approaches to diagnosis and provide clinical and policy decision-makers with the highest possible standard of evidence on which to base diagnostic and treatment decisions. With increasing rates of melanoma and a trend to adopt the use of dermoscopy and other high-resolution image analysis in primary care, the anxiety around missing early cases needs to be balanced against the risk of over referrals, to avoid sending too many people with benign lesions for a specialist opinion. It is questionable whether all skin cancers picked up by sophisticated techniques contribute to morbidity and mortality or whether newer technologies run the risk of increasing false-positive diagnoses. It is also possible that use of some technologies, e.g. widespread use of dermoscopy in primary care with no training, could actually result in harm by missing melanomas if they are used as replacement technologies for traditional history-taking and clinical examination of the entire skin. Many branches of medicine have noted the danger of such "gizmo idolatry" amongst doctors ([Leff 2008](#)). The trend toward remote interpretation of dermatology images (whether clinical or dermoscopic images) and the use of remote technologies that do not involve clinicians without substantive evidence could further disrupt clinical pathways and healthcare payments as they may attract custom from the worried well, leaving an ever decreasing pool of qualified doctors to pick up any resulting problems.

There are few available systematic reviews in the field. The literature searches for the most comprehensive systematic reviews of visual inspection were carried out up to 2007 ([Vestergaard 2008](#)) or are focused on specific clinical questions, for example, specific healthcare professionals ([Corbo 2012](#) including only direct comparisons of the accuracy of primary care physicians versus dermatologists, and [Loescher 2011](#) reviewing the skin cancer detection skills of advanced practice nurses) or settings ([Herschorn 2012](#) including direct comparisons of visual inspection versus dermoscopy in primary care). More recently, Harrington and colleagues ([Harrington 2017](#)) published a systematic review of clinical prediction rules (or published algorithms) used to assist the diagnosis of melanoma; however, the requirement for a clinical prediction rule does not allow comparison of accuracy with and without the use of an algorithm.

The critical question about the accuracy of visual inspection alone and the impact of examiner, prior patient testing, underlying risk status, and the use of images for diagnosis needs to be answered before the potential contribution of additional diagnostic tests can be set in context and appropriately placed in the diagnostic pathway.

This review follows a generic protocol which covers the full series of Cochrane DTA reviews for the diagnosis of melanoma ([Dinnes 2015](#)). The Background and Methods sections of this review therefore use some text that was originally published in the protocol ([Dinnes 2015](#)) and text that overlaps some of our other reviews ([Dinnes 2018](#)).

Objectives

To determine the diagnostic accuracy of visual inspection for the detection of cutaneous invasive melanoma and atypical intraepidermal melanocytic variants in adults.

Accuracy was estimated separately according to the prior testing undergone by study participants:

- i. those with limited prior testing, i.e. primary presentation
- ii. those referred for further evaluation of a suspicious lesion, i.e. referred participants

Accuracy was also estimated separately according to whether the diagnosis was recorded based on a face-to-face (in-person) encounter or based on remote (image-based) assessment.

Secondary objectives

For the identification of cutaneous invasive melanoma and atypical intraepidermal melanocytic variants:

- i. To determine the diagnostic accuracy of individual algorithms used to assist visual inspection; and
- ii. To determine the effect of observer experience on diagnostic accuracy

For the alternative definitions of the target condition:

- iii. To determine the diagnostic accuracy of visual inspection for the detection of invasive melanoma alone in adults.
- iv. To determine the diagnostic accuracy of visual inspection for the detection of any skin cancer or skin lesion with a high risk of progression to melanoma in adults (i.e. requiring excision).

Investigation of sources of heterogeneity

We set out to address a range of potential sources of heterogeneity for investigation across our series of reviews, as outlined in our generic protocol ([Dinnes 2015](#)) and described in [Appendix 5](#); however, our ability to investigate these was necessarily limited by the available data on each individual test reviewed.

The sources of heterogeneity that were investigated for visual inspection were:

- In-person versus image-based evaluations;
- study setting: primary, community or private care versus secondary versus specialist clinics;
- use of a diagnostic algorithm: no algorithm reported versus any named algorithm used;
- type of reference standard: histology alone versus histology plus clinical follow-up or other reference standard; and
- disease prevalence: $\leq 10\%$ versus $>10\%$. The 10% cut-off was chosen based on advice from clinical co-authors (RB, HW).

Methods

Criteria for considering studies for this review

Types of studies

We included test accuracy studies that allow comparison of the result of the index test with that of a reference standard, including the following:

- studies where all participants receive a single index test and a reference standard;
- studies where all participants receive more than one index test(s) and reference standard;
- studies where participants are allocated (by any method) to receive different index tests or combinations of index tests and all receive a reference standard (between-person comparative studies (BPC));
- studies that recruit series' of participants unselected by true disease status (referred to as case series for the purposes of this review);
- diagnostic case-control studies that separately recruit diseased and non-diseased groups (see [Rutjes 2005](#)); however, we did not include studies that compared results for malignant lesions to those for healthy skin (i.e. with no lesion present).
- both prospective and retrospective studies; and
- studies where previously acquired clinical or dermoscopic images were retrieved and prospectively interpreted for study purposes.

We excluded studies from which we could not extract 2x2 contingency data or if they included less than five melanoma cases or less than five benign lesions. The size threshold of five is arbitrary. However, such small studies are unlikely to add precision to the estimate of accuracy.

Participants

We included studies in adults with pigmented skin lesions or lesions suspicious for melanoma or those at high risk of developing melanoma, including those with a family history or previous history of melanoma skin cancer, atypical or dysplastic naevus syndrome, or genetic cancer syndromes.

We excluded studies that recruited only participants with malignant or benign diagnoses.

We excluded studies conducted in children or which clearly reported inclusion of more than 50% of participants aged 16 and under.

Index tests

Studies reporting accuracy data for visual inspection alone, with either image-based or in-person diagnosis, were eligible for inclusion. For in-person visual inspection, diagnosis is undertaken in a clinic setting with the patient present (face-to-face diagnosis). For these studies we assumed that patient history-taking would have taken place and is likely to have contributed to lesion diagnosis; however, we did not specifically extract details of patient history-taking due to anticipated poor reporting in the primary studies. For image-based studies, diagnosis is based on clinical or 'macro' images (photographs), remotely from the study participant. For these studies, any additional patient information that was provided to assist diagnosis was extracted.

All established algorithms or checklists to assist diagnosis by visual inspection were included. Studies developing new algorithms or methods of diagnosis (i.e. derivation studies) were included if they:

- used a separate independent 'test set' of participants or images to evaluate the new approach, or

- investigated lesion characteristics that had previously been suggested as associated with melanoma and the study reported accuracy based on the presence or absence of particular combinations of characteristics.

Studies were excluded if they:

- used a statistical model to produce a data driven equation, or algorithm based on multiple diagnostic features, with no separate test set.
- used cross-validation approaches such as 'leave-one-out' cross-validation ([Efron 1983](#))
- evaluated the accuracy of the presence or absence of individual lesion characteristics or morphological features, with no overall diagnosis of malignancy
- reported accuracy data for 'clinical diagnosis' with no clear description as to whether the reported data related to visual inspection alone
- were based on the experience of a particular skin cancer clinic, where dermoscopy may or may not have been used on an individual patient basis.

Although primary care clinicians can in practice be specialists in skin cancer, we considered primary care physicians as generalist practitioners and dermatologists as specialists. Within each group, we extracted any reporting of special interest or accreditation in skin cancer.

Target conditions

The primary target condition was defined as the detection of:

- any form of invasive cutaneous melanoma or atypical intraepidermal melanocytic variants (i.e. including melanoma in situ, or lentigo maligna, which has a risk of progression to invasive melanoma).

Two additional definitions of the target condition were considered in secondary analyses, namely the detection of:

- any form of invasive cutaneous melanoma alone;
- any skin lesion requiring excision. This latter definition includes melanoma plus other forms of skin cancer, such as basal cell carcinoma (BCC) and cutaneous squamous cell carcinoma (cSCC), as well as melanoma in situ, lentigo maligna, and lesions with severe melanocytic dysplasia.

The diagnosis of the keratinocyte skin cancers, basal cell carcinoma, and squamous cell carcinoma as primary target conditions are the subject of a separate series of reviews ([Dinnes 2015a](#)).

Reference standards

The ideal reference standard is histopathological diagnosis in all eligible lesions. A qualified pathologist or dermatopathologist should perform histopathology. Ideally, reporting should be standardised detailing a minimum dataset to include the histopathological features of melanoma to determine the American Joint Committee on Cancer (AJCC) Staging System (e.g. [Slater 2014](#)). We did not apply reporting of a minimum dataset as a necessary inclusion criterion, but extracted any pertinent information.

Partial verification (applying the reference test only to a subset of those undergoing the index test) was of concern given that lesion excision or biopsy are unlikely to be carried out for all benign-appearing lesions within a representative population sample. Therefore, to reflect what happens in reality, we accepted clinical follow-up of benign-appearing lesions as an eligible reference standard, whilst recognising the risk of differential verification bias (as misclassification rates of histopathology and follow-up will differ).

Additional eligible reference standards included cancer registry follow-up and 'expert opinion' with no histology or clinical follow-up. Cancer registry follow-up is considered less desirable than active clinical follow-up, as follow-up is not carried out within the control of the study investigators. Furthermore, if participant-based analyses as opposed to lesion-based analyses are presented, it may be difficult to determine whether the detection of a malignant lesion during follow-up is the same lesion that originally tested negative on the index test.

All of the above were considered eligible reference standards with the following caveats:

- all study participants with a final diagnosis of the target disorder must have a histological diagnosis, either subsequent to the application of the index test or after a period of clinical follow-up, and
- at least 50% of all participants with benign lesions must have either a histological diagnosis or clinical follow-up to confirm benignity.

Search methods for identification of studies

Electronic searches

The Information Specialist (SB) carried out a comprehensive search for published and unpublished studies. A single large literature search was conducted to cover all topics in the programme grant (see [Appendix 1](#) for a summary of reviews included in the programme grant). This allowed for the screening of search results for potentially relevant papers for all reviews at the same time. A search combining disease-related terms with terms related to the test names, using both text words and subject headings was formulated. The search strategy was designed to capture studies evaluating tests for the diagnosis or staging of skin cancer. As the majority of records were related to the searches for tests for staging of disease, a filter using terms related to cancer staging and to accuracy indices was applied to the staging test search, to try to eliminate irrelevant studies, for example, those using imaging tests to assess treatment effectiveness. A sample of 300 records that would be missed by applying this filter was screened

and the filter adjusted to include potentially relevant studies. When piloted on MEDLINE, inclusion of the filter for the staging tests reduced the overall numbers by around 6000. The final search strategy, incorporating the filter ([Appendix 6](#)), was subsequently applied to all bibliographic databases as listed below. The final search result was cross-checked against the list of studies included in five systematic reviews; our search identified all but one of the studies, and this study is not indexed on MEDLINE. The Information Specialist devised the search strategy, with input from the Information Specialist from Cochrane Skin. No additional limits were used.

We searched the following bibliographic databases to 29 August 2016 for relevant published studies:

- MEDLINE via OVID (from 1946);
- MEDLINE In-Process & Other Non-Indexed Citations via OVID; and
- EMBASE via OVID (from 1980).

We searched the following bibliographic databases to 30 August 2016 for relevant published studies:

- the Cochrane Central Register of Controlled Trials (CENTRAL) Issue 7, 2016, in the Cochrane Library;
- the Cochrane Database of Systematic Reviews (CDSR) Issue 8, 2016 in the Cochrane Library;
- Cochrane Database of Abstracts of Reviews of Effects (DARE) Issue 2, 2015;
- CRD HTA (Health Technology Assessment) database Issue 3, 2016;
- CINAHL (Cumulative Index to Nursing and Allied Health Literature via EBSCO from 1960).

We searched the following databases for relevant unpublished studies:

- CPCI (Conference Proceedings Citation Index) via Web of Science™ (from 1990);
- Zetoc (from 1993)
- SCI Science Citation Index Expanded™ via Web of Science™ (from 1900, using the "Proceedings and Meetings Abstracts" Limit function).

We searched the following trials registers:

- The US National Institutes of Health Ongoing Trials Register (www.clinicaltrials.gov);
- NIHR Clinical Research Network Portfolio Database (<http://www.nihr.ac.uk/research-and-impact/nihr-clinical-research-network-portfolio/>);
- The World Health Organization International Clinical Trials Registry Platform (apps.who.int/trialsearch/).

We aimed to identify all relevant studies regardless of language or publication status (published, unpublished, in press, or in progress). No date limits were applied.

Searching other resources

We have included information about potentially relevant ongoing studies in the 'Characteristics of ongoing studies' tables. We have screened relevant systematic reviews identified by the searches for their included primary studies, and included any missed by our searches. We have checked the reference lists of all included papers, and subject experts within the author team have reviewed the final list of included studies. No citation searching has been conducted.

Data collection and analysis

Selection of studies

Titles and abstracts were screened by at least one author (JDi or NC), with any queries discussed and resolved by consensus. A pilot screen of 539 MEDLINE references showed good agreement (89% with a kappa of 0.77) between screeners. Primary test accuracy studies and test accuracy reviews (for scanning of reference lists) of any test used to investigate suspected melanoma, BCC, or cSCC were included at initial screening. Inclusion criteria ([Appendix 7](#)) were applied independently by both a clinical reviewer (from one of a team of twelve clinician reviewers) and a methodologist reviewer (JDi or NC) to all full text articles, disagreements were resolved by consensus or by a third party (JDe, CD, HW, and RM). Authors of eligible studies were contacted when insufficient data were presented to allow for the construction of 2x2 contingency tables.

Data extraction and management

One clinical (as detailed above) and one methodologist reviewer (JDi, NC or LFR) independently extracted data concerning details of the study design, participants, index test(s) or test combinations and criteria for index test positivity, reference standards, and data required to populate a 2x2 diagnostic contingency table for each index test using a piloted data extraction form. Data were extracted at all available index test thresholds. Disagreements were resolved by consensus or by a third party (JDe, CD, HW, and RM).

Authors of included studies were contacted where information related to final lesion diagnoses or diagnostic threshold were missing. In particular, invasive cSCC (included as disease positive for one of our secondary objectives) is not always differentiated from '*in situ*' variants such as Bowen's disease (which we did not consider as disease positive for any of our definitions of the target condition). Authors of conference abstracts published from 2013 to 2015 were contacted to ask whether full data were available. If no full paper was identified, we marked conference abstracts as 'pending' and will revisit them in a future review update.

Dealing with multiple publications and companion papers

Where multiple reports of a primary study were identified, we maximised yield of information by collating all available data. Where there were inconsistencies in reporting or overlapping study populations, we contacted study authors for clarification

in the first instance. If this contact with authors was unsuccessful, we used the most complete and up-to-date data source where possible.

Assessment of methodological quality

We assessed risk of bias and applicability of included studies using the QUADAS-2 checklist ([Whiting 2011](#)), tailored to the review topic (see [Appendix 8](#)). The modified QUADAS-2 tool was piloted on a small number of included full text articles. One clinical (as detailed above) and one methodologist reviewer (JDi, NC or LFR) independently assessed quality for the remaining studies; any disagreement was resolved by consensus or by a third party where necessary (JDe, CD, HW, and RM).

Statistical analysis and data synthesis

Separate analyses were conducted according to the point that study participants have reached in the clinical pathway (numbered from 1 to 7 in [Figure 3](#)), the clarity with which the pathway could be determined (clear or unclear), and the evaluation of in-person versus image-based diagnosis.

Our unit of analysis was the lesion rather than the patient. This is because (i) in skin cancer initial treatment is directed to the lesion rather than systemically (thus it is important to be able to correctly identify cancerous lesions for each person), and (ii) it is the most common way in which the primary studies reported data. Although there is a theoretical possibility of correlations of test errors when the same people contribute data for multiple lesions, most studies include very few people with multiple lesions and any potential impact on findings is likely to be very small, particularly in comparison with other concerns regarding risk of bias and applicability. Where multiple algorithms were assessed in an individual study, datasets were selected on the following preferential basis:

- i. 'no algorithm' reported; data presented for clinician's overall diagnosis or management decision
- ii. pattern analysis or pattern recognition
- iii. ABCD algorithm (or derivatives of)
- iv. 7-point checklist (also referred to as Glasgow/MacKie checklist)

Where multiple thresholds per algorithm were reported, we included the standard or most commonly used threshold. If data for multiple observers was reported, we used data for the most experienced observer, using single observer diagnosis in preference to a consensus or average across observers. If we were unable to choose a dataset based on the above 'rules', a random selection of one dataset per study was made. Data on the accuracy of dermoscopy, to allow comparisons of tests, was included in a separate review in our series ([Dinnes 2018](#)).

For each analysis, estimates of sensitivity and specificity were plotted on coupled forest plots and in receiver operating characteristic (ROC) space. For tests where commonly used thresholds were reported we estimated summary operating points (summary sensitivities and specificities) with 95% confidence and prediction regions using the bivariate hierarchical model ([Chu 2006](#); [Reitsma 2005](#)). Where inadequate data were available for the model to converge the model was simplified, first by assuming no correlation between estimates of sensitivity and specificity and secondly by setting estimates of near zero variance terms to zero ([Takwoingi 2015](#)). Where all studies reported 100% sensitivity (or 100% specificity) the number with disease (or no disease) was summed across studies and used to compute a binomial exact 95% confidence interval.

For computation of likely numbers of true positive, false positive, false negative and true negative findings in the summary of findings tables, these indicative values were applied to lower quartile, median and upper quartiles of the prevalence observed in the study groups. In summary of findings tables we report these numbers for the average operating point on the SROC curve.

Investigations of heterogeneity

Investigations of heterogeneity, comparisons between algorithms and according to observer experience were made by comparing summary ROC curves using the hierarchical summary receiver-operator curves (HSROC) model ([Rutter 2001](#)). HSROC curves allow incorporation of data at different thresholds and from different algorithms or checklists. We used an HSROC model that assumed a constant SROC shape between tests and subgroups, but allowed for differences in threshold and accuracy by addition of covariates. The significance of the differences between tests or subgroups was assessed by the likelihood ratio test assessing differences in both accuracy and threshold, and by a Wald test on the parameter estimate testing for differences in accuracy alone. Simpler models were fitted when convergence was not achieved due to small numbers of studies, first assuming symmetric SROC curves (setting the shape term to zero), and then setting random effects variance estimates to zero. Estimates of accuracy from HSROC models are presented as diagnostic odds ratios (DORs) (estimated where the SROC curve crosses the sensitivity=specificity line) with 95% confidence intervals. Differences between tests and subgroups from HSROC analyses are presented as relative diagnostic odds ratios (RDORs) with 95% confidence intervals.

Bivariate models were fitted using the `xtnlogit` command in STATA 15 and HSROC models fitted using the `NLMIXED` procedure in the SAS statistical software package ([SAS 2012](#), version 9.3; SAS Institute, Cary, NC, USA) and the `metadas` macro ([Takwoingi 2010](#)).

Sensitivity analyses

Sensitivity analyses, restricting analyses to studies at least risk of bias were planned; however, these were not conducted due to insufficient study numbers.

Assessment of reporting bias

Because of uncertainty about the determinants of publication bias for diagnostic accuracy studies and the inadequacy of tests for detecting funnel plot asymmetry ([Deeks 2005](#)), we did not perform tests to detect publication bias.

Results

Results of the search

A total of 34,347 unique references were identified and screened for inclusion. Of these, 1051 full text papers were reviewed for eligibility for any one of the suite of reviews of tests to assist in the diagnosis of melanoma or keratinocyte skin cancer. Of the 1051 full text papers assessed, 848 were excluded from all reviews in our series (see [Figure 4](#) PRISMA flow diagram of search and eligibility results).

Of the 232 studies tagged as potentially eligible for this review of visual inspection, 49 publications were included reporting 49 individual studies. Exclusions were mainly due to the inability to construct a 2x2 contingency table based on the data presented ($n = 54$); the use of ineligible index tests ($n = 39$) (for example: reporting of data for visual inspection and dermoscopy only ($n = 12$), reporting of data for 'clinical diagnosis' ($n = 11$), or for serial use of the index test in a follow-up context ($n = 7$)); or not meeting our requirements for an eligible reference standard ($n = 23$). Other reasons for exclusion included ineligible study populations ($n = 20$) (for example, recruiting only malignant or only benign lesions ($n = 18$)), inadequate sample size ($n = 14$), ineligible definition of the target condition ($n = 14$) or with test interpretation by medical students or laypersons ($n = 6$). A list of the 183 publications excluded from this review with reasons for exclusion is provided in [Characteristics of excluded studies](#), with a list of all studies excluded from the full series of reviews available as a separate pdf.

The authors of 14 publications were contacted for the purposes of this review of visual inspection and, to date, responses have been received with regard to 7 publications. One response allowed the inclusion of the study in the review ([Walter 2012](#)), five provided clarifications on methods used on studies included ([Bono 2006](#); [Bourne 2012](#); [Rosendahl 2011](#); [Stanganelli 2000](#); [Walter 2012](#)); one replied with the information needed but the two studies could not be included due to the evaluation of 'clinical diagnosis' ([Youl 2007](#); [Youl 2007a](#)); and five replied but were not able to provide the information requested in relation to eight study publications, one which could still be included ([Menzies 2009](#)) and seven which could not ([Fabbrocini 2008](#); [Freeman 1963](#); [Heal 2008](#); [Menzies 2009](#); [Warshaw 2009](#); [Warshaw 2009a](#); [Warshaw 2010](#)).

The 49 included study publications report on a total of 51 cohorts of lesions and 134 datasets with 34,351 lesions and 2499 malignancies. The total number of study participants with suspicious lesions cannot be estimated due to lack of reporting in study publications. Two thirds of studies ($n = 32$; 65%) also reported accuracy data for diagnosis using dermoscopy; these comparisons are reported in [Dinnes 2018](#). Seven studies reported data for additional tests including: teledermatology ($n = 1$) and computer-assisted diagnosis techniques ($n = 6$).

Methodological quality of included studies

The overall methodological quality of all included studies ($n = 49$) is summarised in [Figure 5](#) and [Figure 6](#).

Across almost all study quality domains, insufficient information was provided in the majority of study reports to allow the risk of bias to be judged, while applicability of study findings were scored as of 'High' concern in three of four domains assessed.

For participant selection, only 22% of studies ($n = 11$) were judged at low risk of bias and 27% ($n = 13$) were considered high risk. Ten studies (20%) either used a case-control type design with separate selection of melanoma cases and lesions with benign diagnoses ($n = 6$) or did not clearly describe the study design used ($n = 5$). Over half (55%; $n = 27$) reported random or consecutive participant recruitment reported; the remaining 45% did not describe recruitment methods. Over half of studies (53%) did not describe whether any exclusion criteria were applied and were judged as at unclear risk of bias. Seven studies (14%) applied inappropriate participant exclusions, excluding 'difficult to diagnose' lesions such as awkwardly located lesions ([Bono 2002](#); [Morales Callaghan 2008](#); [Unlu 2014](#)); those with disagreement on histopathology ([de Giorgi 2012](#); [Ek 2005](#); [Zaumseil 1983](#)); or dermoscopically 'peculiar' lesions ([Carli 2003b](#)).

Almost all cohorts (96%; $n = 47$) were considered at high concern for applicability of participants. In the majority of cases ($n = 41$), high concern was due to restricted study populations: inclusion of only melanocytic ($n = 10$) or amelanotic ($n = 1$) lesions; restriction by lesion diameter ([Bono 2002b](#); [Bono 2006](#); [Steiner 1987](#)); or, most commonly, inclusion of lesions selected for excision based on the clinical or dermoscopic diagnosis or selected retrospectively from histopathology databases ($n = 37$). Only four cohorts were judged to have included a representative patient population ([Grimaldi 2009](#); [Menzies 2009](#); [Stanganelli 2000](#); [Walter 2012](#)). Fourteen cohorts also included multiple lesions per participant, with only 8 clearly including similar number of participants and lesions ([Bono 2002](#); [Bono 2002b](#); [Bono 2006](#); [Bourne 2012](#); [Collas 1999](#); [Krahn 1998](#); [Pizzichetta 2004](#); [Unlu 2014](#)).

For the index test domain, studies were considered separately according to whether they reported in-person evaluations of visual inspection ($n = 33$) or evaluations based on interpretation of clinical images (image-based evaluations; $n = 16$). For the in-person evaluations, 24% ($n = 8$) were considered at low risk of bias, and 9% ($n = 3$) were judged high risk; 22 (67%) did not provide sufficient information to allow the risk of bias to be fully judged. All studies were considered to have made the diagnosis blinded to the reference standard result: 24% ($n = 8$) also clearly reported pre-specification of the diagnostic threshold (5 of the 8 using named algorithms ([Argenziano 2006](#); [Cristofolini 1994](#); [Stanganelli 2000](#); [Walter 2012](#); [Zaumseil 1983](#)) and three by the same author team ([Bono 2002](#); [Bono 2002b](#); [Bono 2006](#)) describing the process by which the diagnosis was reached. Three studies developed new algorithms ([Thomas 1998](#)) or evaluated multiple thresholds for test positivity ([Benelli 2001](#); [McGovern 1992](#)).

Reporting was poorer for the image-based evaluations, with over three quarters of studies (n = 13) not providing sufficient information to allow the risk of bias to be fully judged, one study (6%) judged at low risk of bias and two (12%) at high risk. All studies were again considered to have made the diagnosis blinded to the reference standard result, with one prospectively testing two pre-specified diagnostic thresholds ([Benelli 2001](#)) and two ([de Giorgi 2012](#); [Scope 2008](#)) testing multiple diagnostic thresholds.

High concern for the applicability of the index tests was recorded for 85% (n = 28) of in-person evaluations. High concern was primarily due to a lack of description of the diagnostic thresholds used (n = 24), but also as a result of presentation of average ([Argenziano 2006](#)) or consensus diagnoses ([Barzegari 2005](#); [Benelli 1999](#); [Carli 2002](#); [Cristofolini 1997](#); [Morales Callaghan 2008](#); [Steiner 1987](#)) as opposed to the diagnosis of a single observer. Two studies were also judged to have reported diagnosis by non-expert observers ([Menzies 2009](#); [Walter 2012](#)), both of which reported diagnoses by large groups of primary care practitioners. In reality, specific expertise in diagnosing pigmented lesions does vary amongst examiners, for example [Menzies 2009](#) requiring a history of excision or referral of at least 10 pigmented skin lesions over the previous 12-month period but excluding those already using dermoscopy or digital monitoring of lesions, and [Walter 2012](#) excluding those with specialist dermatology training but reporting some training in dermatology for almost a quarter of participating GPs. Almost three quarters of studies (n = 24) were judged to have applied and interpreted the 'test' in a clinically applicable manner, nine (27%) provided sufficient detail of the threshold used and 11 (33%) described the observers as expert or experienced. All image-based studies were of high concern for applicability, due to the image-based nature of interpretation limiting the clinical applicability of findings but also the lack of detail on the thresholds used (n = 13). A higher proportion (62%; n = 10) described the observers as expert or experienced.

Of the 49 included cohorts, 85% were judged at low risk of bias for the reference standard due to the use of an acceptable reference standard (n = 42). Six did not meet our criteria for an acceptable reference standard, with more than 20% of the benign lesions having only expert diagnosis with no clinical follow-up ([Bono 1996](#); [Green 1991](#); [Grimaldi 2009](#); [Menzies 2009](#); [Stanganelli 2000](#); [Walter 2012](#)), three of which were primary care based studies ([Grimaldi 2009](#); [Menzies 2009](#); [Walter 2012](#)). Blinding of the reference standard to the index test (in this case the pathology referral diagnosis) was recorded but did not contribute to the overall risk of bias for the reference standard domain. No blinding of the reference standard was implemented in three studies ([Menzies 2009](#) and [Walter 2012](#) referring patients for excision under standard practice and [Thomas 1998](#) describing a form recording the presence or absence of each ABCDE criterion to the usual pathology form) and blinding was not described in the remaining 46 studies (94%). The applicability of the reference standard was of low concern in 9 studies (18%), high in 7 (14%), and unclear for 33 (67%). In all cases, high concern was due to the use of expert opinion for classifying the final diagnosis of some lesions. The majority of studies (40; 82%) did not report histopathology interpretation by an experienced histopathologist or by a dermatopathologist.

In terms of flow and timing, 20 cohorts were judged at high risk of bias, 7 at low risk and 22 did not provide enough information on which to judge this domain. Of those at high risk, 11 cohorts did not use the same reference standard for all participants (differential verification), and 15 did not include all participants in the analysis either due to incomplete information (n = 7; [Argenziano 2006](#); [Bono 1996](#); [Ek 2005](#); [McGovern 1992](#); [Menzies 2009](#); [Pizzichetta 2004](#); [Walter 2012](#)); inadequate images ([Chang 2013](#); [Dolianitis 2005](#); [Green 1994](#); [Lorentzen 1999](#); [Pizzichetta 2004](#); [Rosendahl 2011](#); [Scope 2008](#)); and exclusion of particular lesion groups following recruitment ([Bourne 2012](#); [Dummer 1993](#); [Menzies 2009](#)). A further 37 cohorts were unclear on the interval between the application of the index test and excision for histology with 12 reporting consecutive diagnosis and excision or biopsy.

Findings

1. Target condition: invasive melanoma and melanocytic intra-epidermal variants

Thirty-seven studies reported accuracy data for the detection of invasive melanoma and melanocytic intra-epidermal variants, one of which reported data for three different sets of lesions ([Morton 1998a](#); [Morton 1998b](#); [Morton 1998c](#)) giving a total of 39 datasets; 28 evaluations were conducted in-person and 11 were image-based.

Summary details of the in-person studies are summarised in [Appendix 9](#), with quality assessments in [Appendix 10](#). Summary details of the image-based studies are summarised in [Appendix 11](#) with quality assessments in [Appendix 12](#). Details of established algorithms used to assist diagnosis are described in detail in [Appendix 4](#). Results for the primary analyses are presented in [Table 1](#). Forest plots of study data for each analysis in [Table 1](#) are given for each analysis in [Figure 7](#) and [Figure 8](#); summary estimates are depicted in [Figure 9](#) and [Figure 10](#). [Table 2](#) reports heterogeneity investigations, [Table 3](#) compares test algorithms and [Table 4](#) compares observers.

In-person evaluations

Of the 28 evaluations conducted on an in-person basis, 17 contained enough information to describe where on the clinical pathway participants were assessed (coded as 'clear' on pathway), and 11 were considered not to have provided sufficient information to allow the pathway to be identified (coded 'unclear' on pathway). These evaluations are considered according to position on the pathway and clear versus unclear pathway classification ([Table 1](#)). [Figure 7](#) presents the results of the individual studies grouped by their position on the pathway; [Figure 9](#) depicts the summary estimates at each point on the pathway.

Studies in participants with limited prior testing

Six in-person evaluations of visual inspection recruited series of participants with pigmented lesions who were presenting for a first structured clinical assessment of a suspicious lesion ([Grimaldi 2009](#); [Menzies 2009](#); [Walter 2012](#); [Collas 1999](#); [Gachon 2005](#); [McGovern 1992](#)) ([Appendix 9](#); [Appendix 10](#)). All studies included participants with pigmented

lesions; [Gachon 2005](#) restricted inclusion to melanocytic lesions only. The prevalence of disease ranged from 4 to 6% in four studies, with [Collas 1999](#) (11%) and [Grimaldi 2009](#) (20%) reporting higher prevalence of melanoma.

Three studies prospectively included all participants presenting in primary care within a given time frame and were clearly positioned on the clinical pathway (Pathway 2-c in [Figure 9](#)):

- summary sensitivity was 92.4% (95% CI: 26.2, 99.8%) and specificity 79.7% (95% CI: 73.7, 84.7%) [1339 lesions and 55 melanomas ([Grimaldi 2009](#); [Menzies 2009](#); [Walter 2012](#))].

Histological diagnosis was supplemented with clinical follow-up of at least 3 months for lesions considered benign (all three studies) and expert clinical diagnosis only without follow-up for some benign lesions ([Menzies 2009](#); [Walter 2012](#)).

Three studies included only participants with lesions selected for excision (Pathway 3-c and 3-u in [Figure 9](#)): two were conducted in private dermatology clinics ([Collas 1999](#); [Gachon 2005](#)) and one at an open access veterans' dermatology clinic ([McGovern 1992](#)) ([Appendix 9](#)):

- summary sensitivity was 90.1% (95% CI: 70.0, 97.3%) and specificity 81.3% (95% CI: 67.5, 90.0%) for two studies clearly positioned on the clinical pathway (Pathway 3-c) [4228 lesions and 160 melanomas ([Gachon 2005](#); [McGovern 1992](#))].
- sensitivity was 78.9% (95% CI: 62.7, 90.4%) and specificity 94.0% (95% CI: 90.7, 96.3%) [353 lesions and 38 melanomas ([Collas 1999](#))] in the single study that could not be clearly positioned on the clinical pathway (Pathway 3-u).

Diagnosis was recorded by primary care physicians with a range of experience ([Grimaldi 2009](#); [Menzies 2009](#); [Walter 2012](#)) or by dermatologists ([Collas 1999](#); [Gachon 2005](#); [McGovern 1992](#)) with no obvious differences in sensitivity or specificity. No formal algorithm to assist diagnosis was reported in four studies; two of which classified lesions 'suspicious for malignancy' as test positive ([Grimaldi 2009](#); [Gachon 2005](#)) and two reported data for 'correct' or 'primary' diagnosis of melanoma' ([Menzies 2009](#); [Collas 1999](#)). [Walter 2012](#) reported data for MacKie's revised 7-point checklist ([MacKie 1990](#)) at a threshold of ≥ 3 , and [McGovern 1992](#) used the BCD algorithm at ≥ 2 characteristics present (this study also reported data using the original 7-point checklist, see Analyses by algorithm reported below).

Studies in referred participants

Twenty-two in-person evaluations of visual inspection were conducted in participants referred for specialist assessment; 12 could be clearly positioned on the clinical pathway (three evaluations from a single study) and 10 did not provide sufficient information for a clear assessment to be made ([Figure 7](#); [Appendix 9](#); [Appendix 10](#)).

Two studies were judged to include all participants referred for further assessment (Pathway 4-c in [Figure 9](#)) and both were clearly positioned on the clinical pathway:

- summary sensitivity was 74.6% (95% CI: 48.9, 90.0%) and specificity 98.6% (95% CI: 94.7, 99.6%) [3494 lesions and 61 melanomas; ([Barzegari 2005](#); [Stanganelli 2000](#))].

Fifteen studies providing 17 datasets included only those with any lesion selected for excision (Pathway 5-c and 5-u in [Figure 9](#)):

- summary sensitivity was 76.7% (95% CI: 61.7, 87.1%) and specificity 95.7% (95% CI: 89.7, 98.3%) (5331 lesions and 258 melanomas) for six studies (with 8 datasets) clearly positioned on the clinical pathway (Pathway 5-c) ([Bono 2002](#); [Bono 2002b](#); [Bono 2006](#); [Ek 2005](#); [Green 1991](#); [Morton 1998a](#); [Morton 1998b](#); [Morton 1998c](#)).
- summary sensitivity was 82.8% (95% CI: 74.4, 88.9%) and specificity 89.2% (95% CI: 71.1, 96.5%) (9611 lesions and 1015 melanomas) for nine studies that could not be clearly positioned on the clinical pathway (Pathway 5-u) ([Benelli 1999](#); [Carli 2002](#); [Cristofolini 1994](#); [Cristofolini 1997](#); [Langley 2001](#); [Morales Callaghan 2008](#); [Thomas 1998](#); [Unlu 2014](#); [Zaumseil 1983](#)).

Three studies were considered to report data only for those participants with equivocal or difficult to diagnose lesions selected for excision (Pathway 5*-c and 5*-u in [Figure 7](#) and [Figure 9](#)):

- summary sensitivity was 84.7% (95% CI: 55.5, 96.1%) and specificity 89.5% (95% CI: 79.5, 95.0%) (930 lesions and 88 melanomas) for two studies clearly positioned on the clinical pathway (Pathway 5*-c) ([Dummer 1993](#); [Soyer 1995](#)).
- sensitivity was 61.4% (95% CI: 49.0, 72.9%) and specificity 87.3% (95% CI: 82.5, 91.2%) (318 lesions and 73 melanomas) in one study not clearly positioned on the clinical pathway (Pathway 5*-u) ([Steiner 1987](#)).

Studies included pigmented lesions referred for further evaluation at a dermatology or pigmented lesion clinic, two restricting to melanocytic lesions only ([Morales Callaghan 2008](#); [Unlu 2014](#)) and four restricting by lesion diameter (≤ 3 mm ([Bono 2006](#)), ≤ 6 mm ([Bono 2002b](#)), < 10 mm ([Steiner 1987](#)), or ≤ 15 mm ([Barzegari 2005](#))). The prevalence of disease ranged from 1% ([Ek 2005](#)) to 41% ([Soyer 1995](#)). Disease prevalence was generally lower in studies clearly positioned on the clinical pathway (11% or less in 7 of 10 datasets) compared to those that could not be clearly positioned (7 of 9 datasets reporting disease prevalence of 15% or over ([Appendix 9](#))). The prevalence of melanoma in studies of equivocal lesions was 3% ([Dummer 1993](#)), 23% ([Steiner 1987](#)) and 41% ([Soyer 1995](#)).

Diagnoses were recorded by dermatologists or dermatology residents (or were assumed to be by dermatologists based on authors' institutions or study settings), by surgical oncologists or by plastic surgeons ([Appendix 9](#)). Observer experience was poorly reported, with only 7 studies referring to 'experienced' or 'expert' observers; three studies were clearly positioned on the pathway and 4 not clearly positioned. Observer diagnosis with no formal algorithm was reported in all studies apart from five using ABCD or ABCDE algorithms ([Benelli 1999](#); [Cristofolini 1994](#); [Cristofolini 1997](#); [Thomas 1998](#); [Stanganelli 2000](#)). Diagnosis was more often based on the opinion of a single observer as

opposed to a consensus or average decision in studies clearly positioned on the pathway (10/12 datasets) ([Stanganelli 2000](#); [Bono 2002](#); [Bono 2002b](#); [Bono 2006](#); [Green 1991](#); [Morton 1998a](#); [Morton 1998b](#); [Morton 1998c](#); [Dummer 1993](#); [Soyer 1995](#)) compared to those not clearly positioned (3/10) ([Thomas 1998](#); [Unlu 2014](#); [Zaumseil 1983](#)).

Image-based evaluations

Of the 11 image-based evaluations, two contained enough information to describe where on the clinical pathway participants were assessed (coded as 'clear' on pathway), and 9 were considered not to have provided sufficient information to allow the pathway to be identified (coded 'unclear' on pathway) ([Appendix 11](#) and [Appendix 12](#)). Results are present in [Table 1](#). [Figure 8](#) presents the results of the individual studies grouped by their position on the pathway; [Figure 10](#) depicts the summary estimates at each point on the pathway.

Studies in participants with limited prior testing

Two studies retrospectively reviewed clinical images from participants with lesions excised in primary care settings (Pathway 3-c and 3-u in [Figure 10](#)):

- sensitivity was 22.2% (95% CI: 2.8, 60.0%) and specificity 70.7% (95% CI: 54.4, 83.9%) (50 lesions and 9 melanomas) in one study clearly positioned on the clinical pathway (Pathway 3-c) ([Bourne 2012](#)).
- sensitivity was 20.7% (95% CI: 8.0, 39.7%) and specificity 96.8% (95% CI: 94.6, 98.2%) (463 lesions and 29 melanomas) in the study not be clearly positioned on the clinical pathway (Pathway 3-u) ([Rosendahl 2011](#)). The study report was unclear as to whether the excisions were undertaken at the primary care practice or in a referral setting.

The prevalence of melanoma was 6% ([Rosendahl 2011](#)) and 20% ([Bourne 2012](#)) and both studies included a range of different types of lesions. Lesion images were reviewed by three GPs and a clinical nurse with varying levels of dermoscopy experience ([Bourne 2012](#)) and by an expert dermatologist ([Rosendahl 2011](#)). Diagnosis was made without the aid of a published algorithm.

Studies in referred participants

Nine evaluations of clinical images were conducted in participants referred for specialist assessment; one could be clearly positioned on the clinical pathway and eight did not provide sufficient information for a clear assessment to be made.

One study clearly positioned on the clinical pathway was considered to have included all participants referred for further assessment (Pathway 4-c in [Figure 10](#)):

- sensitivity was 74.2% (95% CI: 55.4, 88.1%) and specificity 82.5% (95% CI: 73.8, 89.3%) (134 lesions and 31 melanomas ([Stanganelli 2005](#))).

The remaining 8 studies did not provide sufficient information to clearly position them on the clinical pathway but were assumed to have obtained lesion images from referral settings (Pathway 5-u and 5*u in [Figure 10](#)):

- summary sensitivity was 60.3% (95% CI: 49.2, 70.5%) and specificity 77.0% (95% CI: 63.9, 86.4%) (293 lesions and 96 melanomas) for six studies that included all lesions selected for excision (Pathway 5-u) ([Benelli 2001](#); [Carli 2002b](#); [Dolianitis 2005](#); [Pizzichetta 2004](#); [Stanganelli 1998](#); [Winkelmann 2016](#)).
- summary sensitivity was 61.9% (95% CI: 46.7, 75.0%) and specificity 81.8% (95% CI: 75.2, 87.0%) (303 lesions and 98 melanomas) across two studies that included participants with equivocal lesions selected for excision (Pathway 5*u) ([Carli 2003b](#); [de Giorgi 2012](#)).

Studies were retrospective case series apart from two case control type studies ([Winkelmann 2016](#); [Dolianitis 2005](#)) and one with an unclear design ([Benelli 2001](#)). Three studies ([Benelli 2001](#); [Dolianitis 2005](#); [Stanganelli 1998](#)) evaluated observer accuracy before and after dermoscopy training. Images of pigmented or melanocytic lesions were reviewed in all studies apart from one focused on hypomelanotic ($\leq 30\%$ pigmentation) or amelanotic lesions ([Pizzichetta 2004](#)). The prevalence of melanoma ranged from 19% ([Carli 2002b](#)) to 50% ([Dolianitis 2005](#)); four studies included only melanomas (including in situ) and benign naevi ([Carli 2003b](#); [de Giorgi 2012](#); [Stanganelli 2005](#); [Winkelmann 2016](#)).

Lesion diagnosis was undertaken by dermatologists or by observers with mixed qualifications; observer experience was poorly reported ([Appendix 11](#)). [Stanganelli 2005](#) also provided accuracy data for the average of three GPs (data reported in section 1.3.2). Most studies presented average accuracy across observers; only two reported accuracy for a single observer ([Benelli 2001](#); [Pizzichetta 2004](#)). Diagnoses were made without the use of diagnostic algorithms in all studies except [Benelli 2001](#) (ABCDE algorithm) and [de Giorgi 2012](#) (ABCD).

Secondary analyses

Secondary analyses were conducted for the detection of invasive melanoma and melanocytic intra-epidermal variants regardless of classification by clinical pathway.

Covariate investigations

A preliminary analysis across the 39 datasets contributing to the primary analyses described above found a large difference in accuracy for in-person evaluations compared to those based on the assessment of clinical images (relative diagnostic odds ratio (RDOR) 8.54, 95% CI 2.89, 25.3, $P < 0.001$) ([Table 2](#); [Figure 11](#)). The magnitude and importance of the observed difference is so large, raising serious concerns about the applicability of visual inspection studies done via image observation only, that we elected to undertake all subsequent covariate investigations based on in-person evaluations only ($n = 28$).

For the 28 in-person evaluations, only one of the four covariate investigations approached statistical significance ([Table 2](#)); observed accuracy was lower in studies where disease prevalence of melanoma (percentage of cases in the study which tested positive for the reference standard) was over 10% compared to those with disease prevalence of 10% or less (RDOR 0.31, 95% CI 0.09, 1.00; $P = 0.05$). The RDOR for study setting (secondary care or specialist clinic compared to primary care) was 1.51 (95% CI 0.32, 7.09; $P = 0.59$; [Figure 12](#)), for use of a named algorithm to aid diagnosis compared to no algorithm reported was 1.03 (95% CI 0.25, 4.34; $P = 0.96$; [Figure 13](#)), and for use of histology plus clinical follow-up or other reference standard compared to histology alone was 0.76 (95% CI 0.14, 4.02; $P = 0.74$; [Figure 14](#)).

Analyses by algorithms used to assist visual inspection

Of the 28 in-person evaluations only seven reported using an algorithm to assist visual inspection, limiting the ability of meaningful comparisons between algorithms to be made ([Table 3](#)). Observer diagnosis without the use of a formal algorithm ($n = 21$ datasets) had the highest diagnostic accuracy (DOR 46.2, 95% CI 21.9, 97.5), with an average sensitivity of 78% (95% CI 68, 85%) and average specificity 93% (95% CI 88, 96%). Pooled sensitivity was slightly higher and specificity slightly lower for variations on the (A)BCD(E) algorithm ($n = 6$ datasets), but with overlapping confidence intervals (summary sensitivity 83% (95% CI 75, 88%); summary specificity 88% (95% CI 64, 97%)). Two datasets reported data for either the original seven point checklist at a number of thresholds ([McGovern 1992](#)) or for the revised 7 point checklist ([Walter 2012](#)). At the standard threshold of ≥ 3 for both algorithms, the highest observed sensitivity and specificity was 94% (95% CI 73, 100) and 80% (95% CI 77, 83%) for the revised version ([Walter 2012](#)).

The image-based evaluations reported data for either no algorithm or for variations of ABCD(E); a similar pattern was observed with much lower levels of overall accuracy ([Table 3](#)).

Analyses by observer experience

Analyses by observer expertise were restricted by the limited amount of information provided in the study reports ([Table 4](#); [Appendix 9](#) and [Appendix 11](#)). Our analyses are therefore based primarily on study subgroups by observer qualifications (consultant/registrar/mixed qualifications/primary care practitioners), with the 'consultant' category separated into 'Expert consultant' (for any study describing observers as expert or experienced) and 'Consultant' where experience or expertise was not otherwise reported (for example, for those that described observers as dermatologists) ([Table 4](#); [Figure 15](#)).

No clear pattern according to observer experience could be discerned for in-person evaluations. Relative DORs in comparison to the 'Expert consultant' group (9 studies) ranged from 0.45 (95% CI 0.05, 3.67; $P=0.44$) for observers at resident/registrar level (2 studies) to 7.28 (95% CI 0.69, 76.3; $P=0.09$) for GPs (3 studies).

For image-based evaluations, accuracy was highest for the 'Expert consultant' group (DOR 20.5 (95% CI 4.82, 86.9)); relative DORs in comparison to the 'expert' group ranged from 0.18 (95% CI 0.04, 0.90; $P=0.04$) for observers described as 'dermatologists' (4 studies) to 0.56 (95% CI 0.04, 7.51; $P=0.63$) for mixed secondary and primary care observers (1 study).

Across all definitions of the target condition, 7 studies provided comparative data according to observer qualifications or experience ([Table 5](#)). Most were image-based assessments, using no prescribed algorithm to aid diagnosis and reporting average results across groups of observers. Some evidence of increased sensitivity and smaller increases in specificity were observed with increasing experience; however, wide variations in accuracy remained with sensitivity ranging from 58% to 91% for expert dermatologists and specificities from 53% to 99%.

2. Target condition: invasive melanoma only

In this section, we present the results for studies of visual inspection for the identification of invasive melanoma, according to the approach taken for diagnosis: in-person or image-based evaluations. Summary characteristics of studies are presented in [Appendix 13](#) and results of meta-analyses in [Table 6](#), and [Figure 16](#). [Table 7](#) compares results in studies reporting data for invasive melanoma alone and for invasive melanoma plus atypical intraepidermal melanocytic variants.

Seven datasets evaluated the accuracy of in-person visual inspection for the detection of invasive melanoma ([Bono 1996](#); [Green 1994](#); [Kopf 1975](#); [Krahn 1998](#); [McGovern 1992](#); [Vigliizzo 2004](#); [Walter 2012](#)), only two of which also reported data for the primary target condition ([McGovern 1992](#); [Walter 2012](#)). All studies were based in secondary care or specialist units apart from [Walter 2012](#) (primary care) and [McGovern 1992](#) (army medical centre dermatology clinic). Studies used a modified version of the ABCD checklist ([McGovern 1992](#)), the revised 7-point-checklist ([Walter 2012](#)), or no algorithm ($n = 5$; 71%) to assist diagnosis. The prevalence of melanoma ranged from 2% ([Kopf 1975](#); [Walter 2012](#)) to 49% ([Krahn 1998](#)). Two studies supplemented a histological reference standard with clinical follow-up ([Walter 2012](#)) and expert diagnosis of some benign lesions ([Walter 2012](#); [Bono 1996](#)).

Sensitivities ranged from 67% to 100% and specificities ranged from 76% to 100%. In meta-analysis the DOR was 62.4 (95% CI 17.6, 222) (6857 lesions and 208 melanoma cases). Sensitivity and specificity at the average operating point on the SROC curve were 86% (95% CI: 68, 94%) and 91% (95% CI: 81, 96%) respectively. For the two in-person evaluations which also reported data for the primary target condition ([Table 7](#)), specificity estimates were hardly affected due to small numbers of included melanoma *in situ* lesions (5 in [McGovern 1992](#) and 2 in [Walter 2012](#)). Sensitivity however, was higher for detection of invasive melanoma alone in [McGovern 1992](#) (100% versus 73% for detection of invasive melanoma or atypical intraepidermal melanocytic variants) due to correct diagnosis of only two of five *in situ* melanomas, and was marginally lower in [Walter 2012](#) (93.8% versus 94.4% for detection of invasive melanoma or atypical intraepidermal melanocytic variants) due to correct identification of both *in situ* melanomas with one invasive melanoma missed.

Five datasets reported the accuracy of image-based visual inspection for the detection of invasive melanoma ([Lorentzen](#)

1999; Rao 1997; Scope 2008; Troyanova 2003; Westerhoff 2000), but none of which reported data for the primary target condition. Only two studies used images from normal practice settings (Lorentzen 1999; Rao 1997); one obtained images from a teledermatology company (Scope 2008) and two selected images of melanoma cases and controls for use in dermoscopy training studies (Troyanova 2003; Westerhoff 2000). The prevalence of melanoma ranged from 3% (Scope 2008) to 50% (Troyanova 2003; Westerhoff 2000). The ABCD checklist (Rao 1997), the ugly duckling approach (Scope 2008), or no algorithm (n = 3) was used to assist diagnosis. Four evaluations clearly presented only the clinical image with no further patient information (80%), and one (Rao 1997) may have presented observers with a concurrent dermoscopic image of the lesion as blinding between images was not clearly described.

Sensitivities ranged from 62% to 86%; specificities ranged from 54% to 95%. In meta-analysis the DOR was 14.8 (95% CI 3.56, 61.9) [599 lesions and 150 melanoma cases]. Sensitivity and specificity at the average operating point on the SROC curve were 76% (95% CI: 50, 91%) and 83% (95% CI: 62, 93%) respectively.

Accuracy was non-significantly higher for in-person compared to image-based evaluations (RDOR 4.21; 95% CI 0.62, 28.6; P = 0.13).

3. Target condition: any skin lesion requiring excision

In this section, we present the results for studies of visual inspection for the identification of any skin lesion requiring excision (for each study, data could only be extracted for the detection of any skin cancer), according to the approach taken for diagnosis: in-person or image-based evaluations. Summary characteristics of studies are presented in Appendix 14 and results of meta-analyses in Table 6 and Figure 17. Table 7 compares results in studies reporting data for invasive melanoma alone and for invasive melanoma plus atypical intraepidermal melanocytic variants.

Seven datasets evaluated the accuracy of in-person visual inspection for the detection of any skin lesion requiring excision (Argenziano 2006; Chang 2013; Ek 2005; McGovern 1992; Stanganelli 2000; Steiner 1987; Walter 2012), five of which also reported data for the primary target condition (Ek 2005; McGovern 1992; Stanganelli 2000; Steiner 1987; Walter 2012). Three studies were based in primary care (Argenziano 2006; Walter 2012) or community dermatology clinics (McGovern 1992), the others were based in secondary care or specialist referral clinics. The prevalence of skin cancer ranged from 3% (Walter 2012) to 68% (Ek 2005). Studies used the ABCD algorithm (Argenziano 2006; McGovern 1992; Stanganelli 2000), the revised 7-point-checklist (Walter 2012), or no algorithm (n = 3) to assist diagnosis. Two studies supplemented a histological reference standard with clinical follow-up (Stanganelli 2000; Walter 2012) and expert diagnosis of some benign lesions (Walter 2012).

Sensitivities ranged from 57% to 98%; specificities ranged from 13% to 99%. In meta-analysis the DOR was 20.5 (95% CI 7.11, 59.3) (8091 lesions and 2187 skin cancer cases). Sensitivity and specificity at the average operating point on the SROC curve were 81% (95% CI: 68, 90%) and 81% (95% CI: 56, 93%) respectively. For the in-person evaluations which also reported data for the primary target condition (Table 7), specificity estimates were not affected in four of the five studies due to the relatively small percentage of other skin cancers in the study populations (BCCs making up 2% of all lesions in McGovern 1992; 1% in Stanganelli 2000 and Walter 2012; and 6% in Steiner 1987). Sensitivities increased in two studies due to a majority of BCCs correctly identified (Stanganelli 2000; Steiner 1987); sensitivity fell in Walter 2012 due to 3 of 4 BCCs not picked up by the revised seven point checklist; and remained the same in McGovern 1992. A large increase in sensitivity and fall in specificity was observed in Ek 2005, however, as BCCs made up 47% of the total study population and invasive SCCs comprised 20%. When these two lesion groups were considered as disease positive, sensitivity increased from 48% to 98% and specificity fell from 99% to 13% due to the largely correct identification of BCC and SCC as malignant and high false positives in the remaining group of lesions considered disease negative (including large proportions with Bowens disease, solar keratoses, or seborrhoeic keratoses).

Three datasets reported the accuracy of image-based visual inspection for the detection of any skin lesion requiring excision (Carli 2002b; Rosendahl 2011; Stanganelli 1998), all of which also reported data for the primary condition. All studies selected images from normal practice settings, two in secondary care (Carli 2002b; Stanganelli 1998) and one from a primary care practice (Rosendahl 2011). The prevalence of lesions suitable for excision ranged from 22% (Rosendahl 2011) to 47% (Stanganelli 1998); the latter selecting images for use in a dermoscopy training study. Data were presented for a single dermatologist (Rosendahl 2011), a consensus of two dermatologists (Carli 2002b), or the average across 20 dermatologists (Stanganelli 1998). No algorithm was used to assist diagnosis (n = 3) and no further patient information was presented to assist diagnosis.

Sensitivities ranged from 64% to 80%; specificities ranged from 74% to 85%. In meta-analysis the DOR was 11.9 (95% CI 2.22, 65.3) (547 lesions and 138 skin cancer cases). Sensitivity and specificity at the average operating point on the SROC curve were 75% (95% CI: 49, 90%) and 79% (95% CI: 38, 96%) respectively. For the three studies which also reported data for the primary target condition (Table 7), sensitivities increased in two due to correct identification of BCCs (Rosendahl 2011; Stanganelli 1998). Specificity decreased in Carli 2002b due to small sample size and high prevalence of malignancy (20/53; 38%) and decreased in Rosendahl 2011 due to the use of a different threshold for the primary target condition 'is this lesion a melanoma?' compared to 'should this lesion be excised?' for the target condition of any lesion requiring excision.

No significant difference in accuracy between in-person and image-based evaluations was identified (RDOR 1.70; 95% CI 0.24, 12.3; P=0.55).

Discussion

Summary of main results

Summary of main results

Visual inspection has been evaluated in a range of study populations, on an in-person basis and using clinical images, and both with and without the use of published algorithms to assist diagnosis. Wide variations in sensitivity and specificity were observed for all definitions of the target condition.

There are five main findings from our review:

1) There is an almost universal problem with poor reporting in the primary studies, hindering attempts to analyse studies according to their position on the clinical pathway and to fully assess sources of heterogeneity and methodological quality.

Less than two thirds of in-person evaluations of visual inspection contained enough information to describe where on the clinical pathway participants were assessed. This was particularly the case for studies apparently conducted in referred populations, where almost half of studies neither described participants as 'referred', nor provided any description of participants' prior testing or pathway followed prior to presentation for specialist review. Observer experience and expertise in pigmented lesion diagnosis is likely to impact on test accuracy; however, this information was rarely provided in any detail making it difficult to assess any differences in accuracy according to clinician experience. Analyses by reported observer qualifications and descriptions of observers as 'expert' or 'experienced' showed no significant differences between groups.

In terms of methodological quality, studies were at unclear risk of bias due to poor reporting of key items around participant selection, pre-specification of thresholds used, and timing of diagnosis in relation to reference standard diagnosis. Concern around applicability of studies was almost universally poor due to restricted inclusion of lesions and lack of reproducibility of diagnostic thresholds. Given these limitations and the heterogeneity in various aspects of the primary studies, our results cannot be considered conclusive regarding the accuracy of visual inspection for melanoma diagnosis.

2) Prior testing of participants or study position on the clinical pathway does appear to matter.

Focusing on in-person evaluations that could be clearly positioned on the clinical pathway ([Summary of findings table 1](#)), the highest sensitivity (92.4%, 95% CI 26.2, 99.8%) and lowest specificity (79.7%, 95% CI 73.7, 84.7%) for the primary target condition of invasive melanoma or atypical intraepidermal melanocytic variants was observed in three datasets from participants with limited prior testing; however, confidence intervals were wide and heterogeneity high, particularly for sensitivity. Data for referred participants suggest that summary sensitivities fall to around 75%, but with much higher specificities (e.g. sensitivity 76.7% (95% CI 61.7, 87.1%) and specificity 95.7% (95% CI 89.7, 98.3%) for lesions selected for excision, n = 8 datasets). Sensitivity was higher for equivocal lesion populations but with very wide confidence intervals (84.7%, 95% CI 55.5, 96.1%) with summary specificity of 89.5% (95% CI 79.5, 95.0%) (2 datasets).

The general trade-off between sensitivity and specificity along the pathway could be due to differences in the spectrum or 'case mix' of included lesions, differences in the definition of a positive test result, or may be linked to variations in observer expertise. Spectrum effects can be observed when tests that are developed further down the referral pathway have lower sensitivity and higher specificity when applied in settings with participants with limited prior testing ([Usher-Smith 2016](#)). Classic examples include the use of dipstick tests for detection of urinary tract infection (UTI) ([Lachs 1992](#)) and the D-dimer test to detect pulmonary embolism (PE) ([Ginsberg 1993](#)). In both studies, as the prior probability of having UTI or PE increases (and so prevalence of disease increased), test sensitivity increased (from 79% to 93% in [Ginsberg 1993](#), and from 58% to 92% in [Lachs 1992](#)) while specificities decreased (from 76% to 45% in [Ginsberg 1993](#) and from 77% to 42% in [Lachs 1992](#)). However, this direction of effect is not consistent across tests and diseases as [Leeftang 2013](#) clearly demonstrates; the mechanisms in action are often more complex than prevalence alone and can be difficult to identify.

Using disease prevalence as a proxy for disease spectrum, our classification of studies did result in a somewhat lower prevalence of disease (suggesting a wider spectrum of lesion types) in limited prior testing studies (median prevalence 5%, interquartile range (IQR) 3%, 9%) compared to referral settings (median prevalence 15%, IQR 10, 21%), but with overlapping ranges (2% to 11%, and 1% to 41%, respectively). The lower specificity observed in limited prior testing studies is likely related to the presence of a wider range of benign lesions with similar characteristics to melanoma leading to more referrals. Observers in primary care are also likely to have a lower threshold for considering benign lesions as possibly malignant due to the risk of missing true cases of melanoma, contributing both to higher sensitivity and a higher false positive rate. Referred populations on the other hand may have a higher proportion of equivocal or 'difficult to diagnose' melanomas that are difficult to identify.

In terms of eligibility criteria, varying degrees of clinical suspicion of malignancy were required for lesion inclusion in limited prior testing populations ranging from lesions that could not immediately be diagnosed as benign, to there being a requirement for a teledermatology second opinion. In referral populations, eligibility was frequently based on lesion excision, the basis or rationale for which was not described. The restriction to lesions deemed to be suitable for excision will decrease specificity, as more obviously benign lesions would be excluded. The spectrum of lesion types in the disease negative groups also varied across studies, with a number of studies restricting inclusion only to those with melanocytic lesions (such that all benign lesions were benign melanocytic naevi) and others reporting high proportions of other types of skin cancers (BCC or SCC), or of benign keratotic lesions such as seborrheic or actinic keratoses, or of Spitz naevi which may be difficult to differentiate from melanoma.

3) Visual inspection alone is not sufficiently sensitive for the detection of melanoma, and there is no clear evidence that accuracy is improved by the use of any named or published algorithm to assist diagnosis in all settings.

Test sensitivity was greater than 90% (i.e. less than 1 in 10 melanomas missed) in only 6 of the 28 in-person based evaluations of the primary target condition and confidence intervals for the pooled estimates were wide, raising the question

as to whether visual inspection can be relied on to rule out the presence of melanoma. Applying the sensitivity and specificity estimates for the limited prior testing studies cited above to a hypothetical cohort of 1000 lesions at disease prevalence of 4%, 9%, and 16% (see [Summary of findings table 1](#)) shows that visual inspection would *on average* miss 3, 7 or 12 melanomas, with 195, 185 and 171 false positive results (potentially leading to unnecessary excisions or lesion referral or follow-up depending on the anticipated clinical action following a positive result). The wide confidence intervals however mean that the number of melanomas missed could range from between 0 and 118, with false positives from 129 to 252. For a cohort of 1000 lesions in a referred population at prevalence of 4%, 9%, and 16% ([Summary of findings table 1](#)), the pooled sensitivity of 76.7% and specificity 95.7% translate to 9, 21, and 37 melanomas missed on average (range: 5 to 61) and 41, 39, and 36 false positive results (range: 14 to 99).

The evidence to support the use of available algorithms to assist visual inspection was limited, and results are likely to be confounded by patient spectrum and observer experience. Considerable variation in definitions of test positivity across studies that did not report using any algorithm was also observed, i.e. where observer diagnosis was based on observers' own interpretation of lesion characteristics. Where reported, visual inspection was considered to be positive for observers 'correct diagnosis of melanoma', 'suspicion of malignancy', or 'selection for excision', each of which is likely to result in varying proportions of test positive or negative for any given population.

Nevertheless, covariate investigations for the primary analysis across all study settings suggested no difference in accuracy according to the reported use of any named or published algorithm to assist diagnosis. This result was supported by limited subgroup analysis according to algorithm used. Only one eligible study directly compared the accuracy of visual inspection with and without the use of an algorithm ([Collas 1999](#)); however, the authors developed their own new algorithm for the study and found sensitivity to be higher without the use of the algorithm. Comparing different algorithms, [McGovern 1992](#) reported highest sensitivities from the BCD algorithm (any one characteristic present) and the original seven point checklist (at least two characteristics present). Current guidelines in the UK support the use of the revised seven point checklist in primary care ([NICE 2015](#)). A number of studies assessing the revised seven point checklist algorithm did not meet the stringent inclusion criteria for our review ([HealSmith 1994](#); [Higgins 1992](#); [Osborne 1999](#); [Walter 2013](#)); however, the single eligible study using the revised seven point checklist as part of a large randomised controlled trial reported high sensitivity (94%) when used by GPs ([Walter 2012](#)).

4) The definition of the target condition has an effect on diagnostic accuracy.

Results from studies reporting data for more than one definition of the target condition show that sensitivity in particular is affected by the inclusion of, and percentage of, melanoma in situ and BCC lesions considered disease positive. The direction of effect depends on observers' ability to correctly identify these lesions as malignant. It is likely that similar effects impact on results observed across all included studies. Clear identification of the target condition was not provided in 11 of the 28 datasets included in our primary analyses so that the inclusion of melanoma in situ lesions as disease positive was assumed on the basis that the disease positive group was described as 'melanoma' and not as 'invasive melanoma' or 'malignant melanoma'. Of those studies that clearly reported including in situ lesions, the percentage of the disease positive group (invasive melanoma and atypical intraepidermal melanocytic variants) described as being in situ ranged from 10% to 50%. Where studies included other invasive skin cancers (mainly BCCs or SCCs) in the study population (lesions considered disease negative for detection of the primary target), we attempted to class any that were correctly identified by observers as malignant as 'true negative' results as opposed to 'false positives' (thereby increasing observed specificities), on the basis that removal of any skin cancer in the attempt to identify melanomas would not be a negative consequence of the test. Our ability to reclassify lesions relied on studies providing a disaggregation of test results according to final lesion classification and was not always possible, particularly when invasive SCCs were not separated from 'in situ' lesions such as Bowen's disease.

5) There are substantial differences in diagnostic accuracy between in-person and image-based assessments.

Accuracy was much lower and reporting was poorer for evaluations of a diagnosis based on the interpretation of clinical images as opposed to in-person evaluations. Other than possible differences in patient spectrum between in-person and image-based studies, one possible explanation for the observed difference is that even using the highest quality clinical image, a remote assessment is not equivalent to a physical, face-to-face patient to clinician interaction, which will include patient history-taking as well as a total body examination. We were unable to examine any impact from history-taking over and above inspection of the lesion itself; however, history-taking and in particular, assessment of and knowledge of patients' other lesions could have a significant impact on the decision as to whether or not a patient has melanoma ([Grob 1998](#); [Aldridge 2013](#)). Subtle differences in assessing the lesion shape and colour can be done in an in-person consultation, e.g. by stretching the lesion in the axis perpendicular to the skin creases, which may distort the lesion shape, and by altering the light intensity and direction used during lesion inspection. Palpation of the lesion (and regional lymph nodes) is also possible during in-person examination. The fact that image quality is likely to vary between studies, the time taken to review each image is likely to vary, and the considerable variation in supplementary information provided to observers (ranging from no clinical information, to clinical details regarding patient age, gender or lesion site and information on lesion change over time) will have further contributed to variation in accuracy and lower accuracy estimates in comparison to in-person evaluations. Furthermore, the diagnostic context may have a key influence on observer decisions. In a face-to-face diagnostic encounter and for the examination of lesion images for a teledermatology consultation, the clinicians concerned know that their assessment has a direct consequence on patient management and potentially on patient outcomes. The image-based evaluations included in our primary analysis however were not conducted for teledermatology purposes, but were studies using lesion images to compare accuracy between clinical image diagnosis and dermoscopic image diagnosis, or to compare observer or algorithm performance, for example. Observers would have been aware that their assessment of the lesion image was done in an experimental setting, and would not impact on patients; this could

potentially have affected interpretation.

Strengths and weaknesses of the review

The strengths of our review include an in-depth and comprehensive electronic literature search, systematic review methods including double extraction of papers by both clinicians and methodologists, and contact with authors to allow study inclusion or clarify data. A clear analysis structure according to approach to diagnosis, the definition of the target condition, and the patient pathway was adopted to estimate test accuracy in different study populations. A detailed and replicable analysis of methodologic quality was undertaken.

In comparison to other available systematic reviews, our review extends the time period searched for eligible studies to August 2016 (from 2007 in [Vestergaard 2008](#) and from March 2015 in [Harrington 2017](#)), and we include all eligible studies regardless of availability of a direct comparison with dermoscopic examination (as required in [Vestergaard 2008](#)) or requirement for an algorithm or clinical prediction rule to be included ([Harrington 2017](#)). Our stringent application of review inclusion criteria meant that several otherwise eligible studies were excluded. For example, those reporting accuracy data for 'clinical diagnosis' where dermoscopy may or may not have been used to assist diagnosis were excluded on the basis that the contribution of visual inspection of the lesion could not be discerned.

Studies evaluating eligible algorithms (that were included in [Harrington 2017](#)) were excluded from our review, due to lack of data to construct a 2x2 contingency table, the serial use of the algorithm in the context of lesion follow-up, or use of inadequate reference standards. Without these restrictions, the observed data would likely have been considerably more heterogeneous and of poorer methodological quality. At the same time, our inclusion of all studies reporting data for visual inspection means that an overall assessment of observer accuracy could be made regardless of the use of a named algorithm. Harrington and colleagues rightly point out that lower sensitivity associated with the use of a clinical prediction rule "should not prevent [its] use unless usual decisions, made without the rule, are demonstrably better"; however, unless the accuracy of 'usual decisions' is examined, any benefit from the use of an algorithm cannot be established.

The main concerns for the review are a result of the poor reporting of primary studies, in particular forcing some assumptions to be made to allow studies to be split by pathway and in separating studies by the different definitions of the target condition. Our inability to clearly separate studies by pathway is of real concern given the evidence for the effect on accuracy according to the spectrum or case-mix of included participants ([Lachs 1992](#); [Moons 1997](#); [Leeflang 2013](#)).

Finally, observer expertise is key for any diagnostic process based on visual inspection, with both non-analytical pattern recognition (implicit identification) and analytical pattern recognition (using more explicit 'rules' based on conscious analytical reasoning) employed to varying extents between clinicians, according to factors such as experience and familiarity with the diagnostic question ([Norman 2009](#)). A lack of clear reporting of observer training and experience made analysis difficult.

Applicability of findings to the review question

Varying definitions of the eligible study populations and lack of clarity regarding the patient pathway and any prior testing may restrict the applicability of our findings to the clinical setting. Varying definitions of test positivity and lack of reproducibility of diagnostic thresholds, variability in the use of published algorithms, and in observer qualifications and experience, further restrict the transferability of results to a clinical setting.

Authors' conclusions

Implications for practice

Visual inspection is an essential, fundamental component of the assessment of a suspicious skin lesion; however, the evidence suggests that melanomas will be missed if visual inspection is used on its own. The evidence to support its accuracy in the range of settings in which it is used is both flawed and poorly reported, resulting in an inability to produce meaningful summary results and clear pointers as to where visual inspection is most useful. Overall, the use of published algorithms to assist diagnosis does not appear to improve accuracy; however, neither is there sufficient evidence to suggest that the 'no algorithm' approach should be preferred in all settings, e.g. for training junior staff. Further investigation may lend support to the theory that expert observers are more reliant on non-analytical pattern recognition, while attempts to assist analytical pattern recognition are of more benefit for less experienced or more generalist observers.

Implications for research

Despite the vast volume of research that has been funded to evaluate visual inspection, further prospective evaluation of the added value of established algorithms according to the prior testing or diagnostic difficulty of lesions may be warranted. Prospective recruitment of consecutive series of participants and with systematic follow-up of non-excised lesions to avoid over-reliance on a histological reference standard would allow results to be more generalisable to routine practice. A clear identification of the level of training and experience required to achieve good results is also required. Any future research study needs to be clear about the diagnostic pathway followed by study participants prior to study enrolment, and should conform to the updated Standards for Reporting of Diagnostic Accuracy (STARD) guideline ([Bossuyt 2015](#)).

Cochrane Skin editorial base wishes to thank Michael Bigby, who was the Dermatology Editor for this review; and the clinical referees, Andrew Affleck and Chris Bower. We also wish to thank the Cochrane DTA editorial base and colleagues.

Contributions of authors

JD was the contact person with the editorial base.

JD co-ordinated contributions from the co-authors and wrote the final draft of the review.

JD, NC, LFR, DT, KYW, RBA, RA, and MF screened papers against eligibility criteria.

JD and NC obtained data on ongoing and unpublished studies.

JD, NC, LFR, DT, KYW, RBA, RA, and MF appraised the quality of papers.

JD, NC, LFR, DT, KYW, RBA, RA, and MF extracted data for the review and sought additional information about papers.

JD entered data into RevMan.

JD, MJG and JJD analysed and interpreted data.

JD, JJD, NC, LFR, YT and CD worked on the methods sections.

JD, FW, DT, KYW, RBA, RA, MF, RNM and HCW drafted the clinical sections of the background and responded to the clinical comments of the referees.

JD, JJD, CD and YT responded to the methodology and statistics comments of the referees.

KG was the consumer co-author and checked the review for readability and clarity, as well as ensuring outcomes are relevant to consumers.

JD is the guarantor of the update.

Kathie Godfrey: I have received reimbursement of travel expenses incurred by attending meetings.

Fiona M Walter: nothing to declare.

Hywel C Williams: I am director of the NIHR HTA Programme. HTA is part of the NIHR which also supports the NIHR systematic reviews programme from which this work is funded.

Differences between protocol and review

We set out to review visual inspection and dermoscopy for the detection of melanoma in a single review; however, due to the volume of evidence identified, two separate reviews were prepared: one for visual inspection alone and one for dermoscopy, the latter including direct comparisons with visual inspection where both tests were evaluated in the same studies.

Primary objectives and primary target condition have been changed from detection of invasive melanoma alone, to the detection of cutaneous invasive melanoma and atypical intraepidermal melanocytic variants, as the latter is more clinically relevant to the practicing clinician.

Secondary objectives have been tailored to the individual test, with two objectives added: to determine the diagnostic accuracy of individual algorithms for visual inspection; and to determine the effect of observer experience.

Sources of heterogeneity that could be investigated (as listed under [Secondary objectives](#)) were restricted due to lack of data.

Studies using cross-validation, such as 'leave-one-out' cross-validation were excluded rather than included as these methods are not sufficiently robust and are likely to produce unrealistic estimates of test accuracy.

To improve clarity of methods, this text from the protocol "we will include studies developing new algorithms or methods of diagnosis (i.e. derivation studies) if they use a separate independent 'test set' of participants or images to evaluate the new approach. We will also include studies using other forms of cross validation, such as 'leave-one-out' cross-validation ([Efron 1983](#)). We will note for future reference (but not extract) any data on the accuracy of lesion characteristics individually, e.g. the presence or absence of a pigment network or detection of asymmetry" has been replaced with "studies developing new algorithms or methods of diagnosis (i.e. derivation studies) were included if they:

- used a separate independent 'test set' of participants or images to evaluate the new approach, or
- investigated lesion characteristics that had previously been suggested as associated with melanoma and the study reported accuracy based on the presence or absence of particular combinations of characteristics.

Studies were excluded if they:

- used a statistical model to produce a data driven equation, or algorithm based on multiple diagnostic features, with no separate test set.
- used cross-validation approaches such as 'leave-one-out' cross-validation ([Efron 1983](#))
- evaluated the accuracy of the presence or absence of individual lesion characteristics or morphological features, with no overall diagnosis of malignancy
- reported accuracy data for 'clinical diagnosis' with no clear description as to whether the reported data related to visual inspection alone
- were based on the experience of a particular skin cancer clinic, where dermoscopy may or may not have been used on an individual patient basis."

Although we extracted any reporting of special interest or accreditation in skin cancer according to observer expertise, we were unable to analyse the effect on accuracy.

We proposed to supplement the database searches by searching the annual meetings of appropriate organisations (e.g. British Association of Dermatologists Annual Meeting, American Academy of Dermatology Annual Meeting, European Academy of Dermatology and Venereology Meeting, Society for Melanoma Research Congress, World Congress of Dermatology, European Association of Dermato Oncology), however due to volume of evidence retrieved from database searches and time restrictions we were unable to do this.

For quality assessment, the QUADAS-2 tool was further tailored according to the review topic. In terms of analysis, restriction to analysis of per patient data was not performed due to lack of data. Sensitivity analyses were not performed as planned due to lack of data.

Patient Selection

A. Risk of Bias	
Patient Sampling	<p>Study design: Randomised controlled trial allocating primary care physicians to use either visual inspection alone or visual inspection plus dermoscopy (only excised lesions can be included for each arm).</p> <p>Data collection: Prospective</p> <p>Period of data collection May 2003 to Sept 2004</p> <p>Country Italy and Spain</p>
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk

B. Concerns regarding applicability	
Patient characteristics and setting	<p>Inclusion criteria: Patients asking for screening or exhibiting one or more skin tumours as seen during routine physical examination (patient-finding screening) were considered for inclusion; those undergoing excision were included in this review (i.e. those deemed sufficiently suspicious by the Expert evaluation). PCPs were invited to participate in the trial; only those who attended the training sessions and who then screened patients and referred them to the Pigmented Lesion Clinics were randomised.</p> <p>Setting: Primary</p> <p>Prior testing: No prior testing</p> <p>Setting for prior testing: N/A</p> <p>Exclusion criteria: NR</p> <p>Sample size (patients): No. eligible: 3271 patients screened; 1325 patients allocated to Naked Eye observation and 1197 patients allocated to dermoscopy observation; No. included: 162 received histology after Expert evaluation at the PLC</p> <p>Sample size (lesions): 85 in VI arm and 77 in Dermoscopy arm underwent excision</p> <p>Participant characteristics: Based on full sample: mean age 40, range 2-90 (visual inspection group)/ 41, range 3-94 (dermoscopy group). Male 498 (38%): VI group / 451 (38%) dermoscopy</p> <p>Lesion characteristics NR</p>
Are the included patients and chosen study setting appropriate?	No
Did the study avoid including participants with multiple lesions?	Unclear
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	<p>Visual inspection (VI) ABCD (control arm of RCT comparing naked eye examination to naked eye plus dermoscopy)</p> <p>Method of diagnosis: In person diagnosis</p> <p>Prior test data: N/A in-person diagnosis</p> <p>Diagnostic threshold: Qualitative NR; Described in Intro as: simple morphologic features summarized by the asymmetry, border irregularity, color variegation, and diameter 5 mm (ABCD)</p> <p>Diagnosis based on: Average (n=37)</p> <p>Observer qualifications: Primary care physicians</p> <p>Experience in practice: Not described</p> <p>Experience with index test: Not described</p> <p>Other detail: Pre-randomisation all participating PCPs underwent training in ABCD rule for clinical diagnosis and 3-point checklist for dermoscopy.</p> <p>Dermoscopy: evaluated in intervention arm of trial only.</p>
-------------	---

Visual Inspection - in-person

A. Risk of Bias	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
If a threshold was used, was it pre-specified?	Yes
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	Low risk

B. Concerns regarding applicability	
Was the test applied and interpreted in a clinically applicable manner?	No
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	Yes
Was the test interpretation carried out by an experienced examiner?	Unclear
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High

Visual inspection - image-based

A. Risk of Bias	
B. Concerns regarding applicability	

Reference Standard

A. Risk of Bias	
Target condition and reference standard(s)	<p>Reference standard Histological diagnosis alone</p> <p><i>Details:</i> All lesions considered suggestive of skin cancer at the PLC were excised and subsequently diagnosed histopathologically. Equivocal lesions by histopathologic examination were reviewed by a second independent pathologist and a final diagnosis made.</p> <p>Disease positive: 92 malignant tumours; Disease negative: 70 benign tumours</p> <p>Target condition (Final diagnoses)</p> <p>Melanoma (in situ and invasive, or not reported): 12; BCC: 66; cSCC: 14</p> <p>Seborrheic keratosis: 13; Melanocytic nevi 51; Other: 6</p>
Is the reference standards likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability	
Expert opinion (with no histological confirmation) was not used as a reference standard	Yes
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Yes
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern

Flow and Timing

A. Risk of Bias	
Flow and timing	<p>Excluded participants: Data can only be extracted for those with histology (i.e. patients considered to have lesions suggestive of skin cancer); remainder had expert diagnosis (not included in the final 2x2 data extracted)</p> <p>Time interval to reference test: Not reported</p>
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	
Could the patient flow have introduced bias?	High risk

Patient characteristics and setting	Inclusion criteria: Pigmented skin lesions with a clinical diagnosis of melanocytic lesion <=15mm diameter referred to dermatology clinic for diagnostic evaluation or cosmetic reasons Setting: Secondary (general dermatology) Prior testing: Clinical suspicion of malignancy without dermatoscopic suspicion; Patient request for evaluation/excision Setting for prior testing: Not reported Exclusion criteria: None reported Sample size (patients): No. included: 91 Sample size (lesions): No. included: 122 Participant characteristics: Mean age 32.3 (6-94y); Male: 30; 33% Lesion characteristics NR
Are the included patients and chosen study setting appropriate?	Unclear
Did the study avoid including participants with multiple lesions?	No
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	Visual inspection (VI) No algorithm Method of diagnosis: In person diagnosis Prior test data: N/A in-person diagnosis Diagnostic threshold: Qualitative Melanoma likely (i.e. melanoma first in list of considered diagnoses)/ Melanoma possible (melanoma one of a number of diagnoses) Diagnosis based on: Consensus (2 observers); n=2 Observer qualifications: Dermatology registrar (Dermatology resident (3rd year)); Dermatologist Experience in practice: Mixed experience (low and high experience combined) Experience with index test: Mixed (low and high experience combined)
-------------	---

Visual Inspection - in-person

A. Risk of Bias	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
If a threshold was used, was it pre-specified?	Unclear
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	Unclear risk

B. Concerns regarding applicability	
Was the test applied and interpreted in a clinically applicable manner?	No
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	No
Was the test interpretation carried out by an experienced examiner?	Unclear
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High

Visual inspection - image-based

A. Risk of Bias	
B. Concerns regarding applicability	

Reference Standard

A. Risk of Bias	
Target condition and reference standard(s)	Reference standard Histological diagnosis alone Disease positive: 6; Disease negative: 116 Target condition (Final diagnoses) Melanoma (invasive): 3; Melanoma (in situ): 3 Seborrheic keratosis: 2; Benign naevus: 104; Dysplastic naevus 7 DF 1 AK
Is the reference standards likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability	
Expert opinion (with no histological confirmation) was not used as a reference standard	Yes
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear

Flow and Timing

A. Risk of Bias	
Flow and timing	Excluded participants: None; Time interval between index and reference: Unclear Time interval between index test(s): Consecutive
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	No
Could the patient flow have introduced bias?	Unclear risk

B. Concerns regarding applicability	
Was the test applied and interpreted in a clinically applicable manner?	Yes
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	No
Was the test interpretation carried out by an experienced examiner?	Unclear
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High

Visual inspection - image-based

A. Risk of Bias

B. Concerns regarding applicability

Reference Standard

A. Risk of Bias

<p>Target condition and reference standard(s)</p>	<p>Reference standard Histological diagnosis alone Details: The slides were evaluated according to widely accepted criteria for the histopathological diagnosis of the various pigmented lesions. Disease positive: 23; Disease negative: 183 Target condition (Final diagnoses) Melanoma (invasive): 19 (9.2%); Melanoma (in situ): 4 (2.0%) Mild/moderate dysplasia: dysplastic naevus 10 (4.9%); junctional naevus 76 (36.9%); compound naevus 50 (24.3%); dermal naevus 12 (5.8%); blue naevus 11 (5.3%); reed naevus 7 (3.4%); spitz naevus 3 (1.5%); halo naevus 3 (1.5%); lentigo simplex 7 (3.4%); other 4 (1.9%)</p>
Is the reference standards likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability

Expert opinion (with no histological confirmation) was not used as a reference standard	Yes
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear

Flow and Timing

A. Risk of Bias

<p>Flow and timing</p>	<p>Excluded participants: none Time interval to reference test: not reported</p>
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	
Could the patient flow have introduced bias?	Unclear risk

Patient Selection

A. Risk of Bias	
Patient Sampling	Study design: Case series Data collection: Retrospective image selection / Prospective interpretation Period of data collection June 1 - July 6 2009 Country Australia
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk

B. Concerns regarding applicability	
Patient characteristics and setting	Inclusion criteria: All skin lesions consecutively excised at a skin cancer practice to exclude skin cancer and common lesions assessed as clearly benign and not biopsied were included Setting: Primary Prior testing: Clinical and/or dermatoscopic suspicion. Prior testing to assemble the test set occurs in secondary care by an experienced skin cancer doctor, then the images are tested on primary care professionals Setting for prior testing: Specialist unit (skin cancer/pigmented lesions clinic) Exclusion criteria: Clinically obvious basal cell carcinomas which could be easily diagnosed without dermoscopy were not included in the collection set. Sample size (patients): No. eligible: 46/ No. included: 46 Sample size (lesions): No. eligible: 50/No. included: 50 Participant characteristics: Mean age: 58 (30 to 60); Male: 22 Lesion characteristics: Face = 8; Neck = 1; Chest = 3; Back = 21; Shoulder = 2; Arm = 3; Thigh = 4; Leg = 7; Foot plantar = 1
Are the included patients and chosen study setting appropriate?	No
Did the study avoid including participants with multiple lesions?	Yes
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	Visual inspection (VI) No algorithm Method of diagnosis: Clinical photographs Prior test data: No further information used; Image assessments were done on four occasions, each time using a different diagnostic approach. Diagnostic threshold: Not reported clinicians provided with Excel answer sheets for each method listing the various criteria used in that algorithm but no algorithm was cited for VI Diagnosis based on: Average (n=4) Observer qualifications: 3 GPs and 1 clinical nurse Experience in practice: Mixed; described as varying levels of dermatoscopic experience Dermoscopy: evaluated in same study; 3-point rule; Menzies criteria
-------------	---

Visual Inspection - in-person

A. Risk of Bias
B. Concerns regarding applicability

Visual inspection - image-based

A. Risk of Bias	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
If a threshold was used, was it pre-specified?	Unclear
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	Unclear risk

B. Concerns regarding applicability	
Was the test applied and interpreted in a clinically applicable manner?	No
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	No
Was the test interpretation carried out by an experienced examiner?	Unclear
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High

Reference Standard

A. Risk of Bias	
Target condition and reference standard(s)	<p>Reference standard Histological diagnosis plus other Histopathological examination (n=46); Expert diagnosis as benign (n=3); Digital follow up (n=1)</p> <p>Target condition (Final diagnoses)</p> <p>Melanoma (invasive): 1; Melanoma (in situ): 7; BCC: 6; Lentigo maligna 1</p> <p>Seborrheic keratosis: 5; 'Benign' diagnoses: Banal nevus 10, Blue naevus 1, Nevus and seborrheic keratosis/solar lentigo collision 3, Solar lentigo 4, LPLK 4, Dermatofibroma 1, Psoriasis 1, Solar keratosis 2, Intraepidermal carcinoma 3, Regressed keratoacanthoma 1</p>
Is the reference standards likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Yes
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability	
Expert opinion (with no histological confirmation) was not used as a reference standard	No
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear
Are there concerns that the target condition as defined by the reference standard does not match the question?	High

Flow and Timing

A. Risk of Bias	
Flow and timing	Excluded participants: As two of the methods (Menzies and 3 point checklist) related to only pigmented lesions, the 5 non-pigmented specimens in the set of 50 were excluded from the contingency tables for these methods. Time interval to reference test: "all skin lesions consecutively excised to exclude skin cancer were recorded"
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	No
Were all patients included in the analysis?	No
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	Unclear
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	Yes
Could the patient flow have introduced bias?	High risk

Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Unclear risk

B. Concerns regarding applicability	
Patient characteristics and setting	Inclusion criteria: Patients with pigmented lesions presenting during a campaign for the early diagnosis of cutaneous melanoma at the Dermatology Department in Trento Setting: Secondary (general dermatology) Prior testing: Not reported Setting for prior testing: Not reported Exclusion criteria: Lesions that were not taken into consideration included benign lesions, naevi of Unna and Miescher types and naevi that showed no inclusion criteria at the ABCDE clinical examination Sample size (patients): No. eligible: 700 people; No. included: not reported Sample size (lesions): No. eligible: 220; No. included: 220 Participant characteristics: None reported Lesion characteristics: None reported
Are the included patients and chosen study setting appropriate?	No
Did the study avoid including participants with multiple lesions?	Unclear
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	<p>Visual inspection (VI) ABCDE</p> <p>Method of diagnosis: In person diagnosis</p> <p>Prior test data: N/A in-person diagnosis</p> <p>Other test data: Dermoscopy undertaken by same clinician(s) subsequent to clinical evaluation</p> <p>Diagnostic threshold: lesions showing at least two of the ABCDE criteria all of which were shown the same diagnostic importance, were considered positive.</p> <p>Diagnosis based on: Unclear; n=4</p> <p>Observer qualifications: Dermatologist</p> <p>Experience in practice: High experience or 'Expert'; all trained in the recognition of pigmented lesions during a training course about the clinical diagnosis of naevi and melanomas; all working in a department where the early diagnosis of melanoma had been dealt with for over 10 years.</p> <p>Experience with dermoscopy: High experience /'Expert' users</p> <p>Other detail: ABCDE criteria are (asymmetry in shape, border irregular and notched, colour mottled-haphazard display, dimension >6mm, evolution changes in pigmentation)</p> <p>Dermoscopy: evaluated in same study; Pattern analysis</p>
-------------	---

Visual Inspection - in-person

A. Risk of Bias	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
If a threshold was used, was it pre-specified?	Yes
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Was the test applied and interpreted in a clinically applicable manner?	Unclear
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	Yes
Was the test interpretation carried out by an experienced examiner?	Yes
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	Unclear

Visual inspection - image-based

A. Risk of Bias
B. Concerns regarding applicability

Reference Standard

A. Risk of Bias	
Target condition and reference standard(s)	<p>Reference standard Histological diagnosis alone</p> <p>Target condition (Final diagnoses)</p> <p>Melanoma (in situ and invasive, or not reported): 33</p> <p>Mild//moderate dysplasia: 23 dysplastic naevi; Seborrheic keratosis: 4; Benign naevus: 158 common naevus</p> <p>Other: 2 thrombosed angiomas</p>
Is the reference standards likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Expert opinion (with no histological confirmation) was not used as a reference standard	Yes
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear

Flow and Timing

A. Risk of Bias	
Flow and timing	Excluded participants: No exclusions reported Time interval to reference test: Not described Time interval between index tests: clinical evaluation directly followed by dermoscopy
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	
Could the patient flow have introduced bias?	Unclear risk

Patient Selection

A. Risk of Bias	
Patient Sampling	Study design: Case series Data collection: Prospective Period of data collection January 2001 to December 2002 Country Australia
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	No
Could the selection of patients have introduced bias?	High risk
B. Concerns regarding applicability	
Patient characteristics and setting	Inclusion criteria: Lesions excised at tertiary referral centre for the management of cancers; only those lesions in which malignancy could not be excluded were included Setting: Specialist unit (skin cancer/pigmented lesions clinic) Prior testing: Selected for excision (no further detail) Setting for prior testing: Specialist unit (skin cancer/pigmented lesions clinic) Exclusion criteria: Punch, shave or incisional biopsies and palliative excisions. Equivocal pathology report (n=56). Sample size (patients): No. eligible: 1302; No. included: 1223 Sample size (lesions): No. eligible: 2678; No. included: 2582 Participant characteristics: Mean age: 73.6y (16–102y). Male: 784 (64.1%); History of melanoma/skin cancer (%) 224; 8.7% recurrent lesions Lesion characteristics: Head/Neck: 61%; Trunk: 14.4%; Limbs: 24.6%
Are the included patients and chosen study setting appropriate?	Unclear
Did the study avoid including participants with multiple lesions?	No
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	Visual inspection (VI) No algorithm Method of diagnosis: In person diagnosis Prior test data: N/A in-person diagnosis Diagnostic threshold: Not reported pre-operative diagnosis Diagnosis based on: Unclear; Likely single (n= 5). Observer qualifications: Three consultants, a plastic surgery trainee and a clinical assistant. Experience in practice: Mixed (low and high experience combined); Plastic surgery trainee usually 1st year, on 6 month rotation; clinical assistant described as having “many years of experience”. Other detail: Some results are presented for consultant, senior registrar and registrar but underlying patient numbers are not provided per observer to allow separate 2x2 estimation. The discussion does describe the “six MM misdiagnosed as benign ... as .. assessed by non-consultants”.

Reference Standard

A. Risk of Bias	
Target condition and reference standard(s)	<p>Reference standard Histological diagnosis alone</p> <p>Disease positive: 149; Disease negative: 3887</p> <p>Target condition (Final diagnoses)</p> <p>Melanoma (in situ and invasive, or not reported): 149 (36 were <i>in situ</i> or other invasive lesions with a median Breslow thickness of 0.60 mm)</p> <p>'Benign' diagnoses: 3629 nevi (89.9%); 4 uncertain MMs/nevi (0.1%); and 254 non-melanocytic lesions clinically considered to be nevi or MMs (6.3%).</p>
Is the reference standards likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk
B. Concerns regarding applicability	
Expert opinion (with no histological confirmation) was not used as a reference standard	Yes
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear

Flow and Timing

A. Risk of Bias	
Flow and timing	Excluded participants: None reported Time interval to reference test: NR
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	
Could the patient flow have introduced bias?	Unclear risk

Green 1991

Patient Selection

A. Risk of Bias	
Patient Sampling	Study design: Case series Data collection: Prospective Period of data collection Feb 1989 - Aug 1990 Country Australia
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk

B. Concerns regarding applicability

Patient characteristics and setting	<p>Inclusion criteria: Pigmented lesions with complete clinical and histological data</p> <p>Setting: Secondary (referred from surgery, dermatology, casualty)</p> <p>Prior testing: Not reported</p> <p>Setting for prior testing: Depts surgery, dermatology, casualty</p> <p>Exclusion criteria: None reported</p> <p>Sample size (patients): No. eligible: 81 / No. included: unclear</p> <p>Sample size (lesions): No. eligible: 89; No. included: 70</p> <p>Participant characteristics: Median age 32 yrs; Male 36 (44%)</p> <p>Lesion characteristics: site Trunk: 80%; - Limbs: 10%; - face and neck 10%</p>
Are the included patients and chosen study setting appropriate?	No
Did the study avoid including participants with multiple lesions?	Unclear
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	<p>Visual inspection (VI); No algorithm</p> <p>Method of diagnosis: In person diagnosis</p> <p>Prior test data: In person</p> <p>Diagnostic threshold: Not reported clinical diagnosis recorded plus assessment of diameter, colour, regularity of outline, diffuseness of edge and palpability</p> <p>Diagnosis based on: Single observer; (n= NR)</p> <p>Observer qualifications: Mixed; "in the majority of cases a surgeon or a dermatologist"</p> <p>Experience in practice: Not described</p>
-------------	--

Visual Inspection - in-person

A. Risk of Bias	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
If a threshold was used, was it pre-specified?	Unclear
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Was the test applied and interpreted in a clinically applicable manner?	Yes
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	No
Was the test interpretation carried out by an experienced examiner?	Unclear
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High

Visual inspection - image-based

A. Risk of Bias
B. Concerns regarding applicability

Reference Standard

A. Risk of Bias	
Target condition and reference standard(s)	<p>Reference standard; Histological diagnosis and Expert diagnosis</p> <p><i>Histology:</i> 62/70 lesions</p> <p>Expert diagnosis: 8/70 lesions; Eight lesions had clinical diagnoses assigned (all benign) in the absence of available histology reports</p> <p>Target condition (Final diagnoses)</p> <p>Melanoma (in situ and invasive, or not reported): 5</p> <p>BCC: 2; Seborrheic keratosis: 7; Benign naevus: 53 Other: 2 skin tags, 1 'lentigo'</p>
Is the reference standards likely to correctly classify the target condition?	No
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	High risk
B. Concerns regarding applicability	
Expert opinion (with no histological confirmation) was not used as a reference standard	No
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear
Are there concerns that the target condition as defined by the reference standard does not match the question?	High

Flow and Timing

A. Risk of Bias	
Flow and timing	<p>Excluded participants: 19/89 lesions excluded due to incomplete clinical and histology records.</p> <p>Time interval to reference test: Assumed consecutive; pathology referral form used to ascertain clinical diagnosis</p>
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	No
Were all patients included in the analysis?	No
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?

B. Concerns regarding applicability	
Patient characteristics and setting	Inclusion criteria: Patients with lesions suspicious for CMM referred to outpatients clinic Excluded participants: none reported Time interval to reference test: not reported Setting: Not reported Prior testing: Clinical suspicion of malignancy without dermatoscopic suspicion Setting for prior testing: Not reported Exclusion criteria: Poor quality index test image (considered under flow/timing) Sample size (patients): No. eligible: 242; No. included: 232 Sample size (lesions): No. eligible: 242; No. included: 232* Participant characteristics: None reported Lesion characteristics: None reported *NB Not all cases were assessed by all observers; 2x2 are based on presented sensitivity and specificity estimates for full dataset of lesions; "the dermatoscopy experts assessed almost all cases (98 ± 100%), whereas the non-expert group completed fewer assessments, from 76 to 98%.
Are the included patients and chosen study setting appropriate?	No
Did the study avoid including participants with multiple lesions?	Unclear
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	Visual inspection (VI) No algorithm Method of diagnosis: Clinical photographs Prior test data: No further information used; no option to change clinical diagnosis after viewing dermoscopic image Other test data: Dermoscopic images presented to observer subsequent to diagnosis using clinical images alone; clinical images presented before dermoscopic images Diagnostic threshold: Not reported; clinical diagnosis Diagnosis based on: Average; n= 9 Observer qualifications: Dermatologist Experience in practice: High; Moderate; Mixed (average reported); 4 'experienced dermatologists' (4-5 years daily experience) & 5 'non-expert dermatology residents' (1-2 years interest and formal training in dermatoscopy) Experience with index test: High; Moderate; Mixed
-------------	--

A. Risk of Bias

B. Concerns regarding applicability

Visual inspection - image-based

A. Risk of Bias

Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
If a threshold was used, was it pre-specified?	Unclear
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	Unclear risk

B. Concerns regarding applicability

Was the test applied and interpreted in a clinically applicable manner?	No
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	No
Was the test interpretation carried out by an experienced examiner?	Yes
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High

Reference Standard

A. Risk of Bias

Target condition and reference standard(s)	Reference standard Histological diagnosis alone Disease positive: 65 ; Disease negative: 167 Target condition (Final diagnoses) Melanoma (invasive): 49 'malignant melanoma' BCC: 16 Seborrheic keratosis: 12; Benign naevus: 137 (pigmented nevi=116; blue nevi=16; atypical nevi=5); Other: 18 (spitz nevi, Bowen's disease, sarcoid, nevus spilus, hemangioma, and others)
Is the reference standards likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability

Expert opinion (with no histological confirmation) was not used as a reference standard	Yes
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear

Flow and Timing

A. Risk of Bias

Flow and timing	Excluded participants: 10 cases were "considered unfit for evaluation" due to poor quality image Reference interval: "biopsy specimens...were obtained after the clinical and dermatoscopic photographs had been performed"
Was there an appropriate interval between index test and reference standard?	Yes
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	No
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	
Could the patient flow have introduced bias?	High risk

Patient Selection

A. Risk of Bias

Patient Sampling	<p>Study design: Case series</p> <p>Data collection: Prospective</p> <p>Period of data collection: Between 1 Nov 1989 and 31 Oct 1990</p> <p>Country: USA</p>
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk

B. Concerns regarding applicability

Patient characteristics and setting	<p>Inclusion criteria: Pigmented lesions excised to rule out dysplasia, lentigo maligna or malignant melanoma</p> <p>Setting: Secondary (general dermatology); Army Dermatology clinic - appears to be open access</p> <p>Prior testing: No prior testing. Multiple reasons given for seeking dermatological consultation, including (in descending order): increasing size, "mole check", inflammation, color change, itch, follow-up, variegation, cosmetic, referral, irregular border, seen for other lesion, unknown, large size</p> <p>Setting for prior testing: N/A</p> <p>Exclusion criteria: None reported</p> <p>Sample size (patients): No. eligible: 179; No. included: Not reported</p> <p>Sample size (lesions): No. eligible: 237; No. included: 13 lesions excluded and 32 lesions unaccounted for.</p> <p>Participant characteristics: Mean age: 44 (SD 18); Range: 3 months to 86 years; Male: 89 (49%)</p> <p>Lesion characteristics: lesion site: head/neck: 71 (30%); trunk: 52 (23%); upper limbs/shoulder: 22 (9%); lower limbs/hip: 33 (14%); back = 58 (24%); genitalia = 1 (0.4%)</p>
Are the included patients and chosen study setting appropriate?	Unclear
Did the study avoid including participants with multiple lesions?	No
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	<p>Visual inspection (VI) ABCD; Assessed only 'BCD'; also referred to in paper as 3 point checklist; Glasgow/MacKie original seven-point checklist (Keefe 1990)</p> <p>Method of diagnosis: In person diagnosis</p> <p>Prior test data: Unclear</p> <p>Diagnostic threshold: Described in detail; ABCD excluded 'Asymmetry' -one half does not match the other half)</p> <p>Diagnosis based on: Single observer in clinic diagnoses used (n=NR)</p> <p>Observer qualifications: Not reported likely dermatologists</p> <p>Experience in practice: Not described</p> <p>Any other details: Border irregularity- edges are ragged, notched, or blurred; Color irregularity- pigmentation is not uniform; shades of tan, brown and black are present with dashes of red, white, or blue; Diameter- greater than 6 mm, the size of a pencil eraser</p> <p>7-point: Increasing size, Variegation, Inflammation, Irregular outline, Greater than 1cm diameter, Itch, Bleeding One point awarded for each feature</p>

Menzies 2009

Patient Selection

A. Risk of Bias	
Patient Sampling	<p>Study design: Case series</p> <p>Data collection: Prospective</p> <p>Period of data collection December 2005 to August 2006</p> <p>Country Australia</p>
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk

B. Concerns regarding applicability	
Patient characteristics and setting	<p>Inclusion criteria: Pigmented lesions which, after routine naked eye examination by the GP, would have been biopsied or referred, i.e. a SPL (suspicious pigmented lesion). GPs were recruited from practices with at least 3 clinicians; excluded if they already used dermoscopy or SDDI in their routine practice.</p> <p>Setting: Primary</p> <p>Prior testing: Clinical suspicion of malignancy without dermatoscopic suspicion</p> <p>Setting for prior testing: Primary</p> <p>Exclusion criteria: None reported</p> <p>Sample size (patients): NR</p> <p>Sample size (lesions): No. included: 374</p> <p>Participant characteristics: None reported</p> <p>Lesion characteristics: None reported</p>
Are the included patients and chosen study setting appropriate?	Yes
Did the study avoid including participants with multiple lesions?	Unclear
Are there concerns that the included patients and setting do not match the review question?	Unclear

Index Test

Index tests	<p>Visual inspection (VI) No algorithm</p> <p>Method of diagnosis: In person diagnosis</p> <p>Prior test data: N/A in-person diagnosis</p> <p>Other test data: clinical diagnosis and placed in a sealed envelope before proceeding to dermoscopy examination</p> <p>Diagnostic threshold: Not reported; initial diagnosis recorded along with confidence of diagnosis (scale 1 to 10; 1 not at all confident and 10 extremely confident), certainty of melanoma (scale 0 to 100%; 0 definitely not melanoma and 100 definitely melanoma) and management (biopsy, referral).</p> <p>Diagnosis based on: Single observer (n=63; 102 GPs initially recruited; 74 (72.5%) completed the educational intervention and online assessment; 63 GPs from 19 practices finally participated)</p> <p>Observer qualifications: GP</p> <p>Experience in practice: Not fully described; assumed to be low experience with pigmented lesions. GPs must have each excised or referred ≥ 10 PSL in previous 12-month period; excluded if dermoscopy or SDDI already used in routine practice. During the pretrial period all GPs underwent a training programme in the use of dermoscopy.</p> <p>Dermoscopy: evaluated in same study; no algorithm</p>

Visual inspection - image-based

A. Risk of Bias	
-----------------	--

B. Concerns regarding applicability

Reference Standard

A. Risk of Bias

<p>Target condition and reference standard(s)</p>	<p>Reference standard Histological diagnosis plus other <i>Histology (not further described):</i> described as to standard practice and not necessarily blinded to the GP's diagnosis; author confirmed that all melanoma had histological diagnosis and >50% of benign had histology or follow-up</p> <p>Total excised or referred: 163. Immediate excision/referral: 110. Excision/referral after SDDI: 48. Excision/examination after patient self referral 5</p> <p>Disease positive: 37; Disease negative: total of 126 benign or unknown were 'excised OR referred' so some would have had specialist dx only.</p> <p><i>Clinical FU plus histology of suspicious lesions:</i> Short term digital monitoring (SDDI) available as an option for lesions considered not to be melanoma but that were still considered suspicious; follow-up imaging occurred initially at 3 months with any morphological changes to result in biopsy or referral; some lesions continued SDDI for a further 3 months; Length of FU: 3-6 months</p> <p>No. patients: Initially recommended for SDDI: 192; SDDI continued for further 3 months: 6; Underwent SDDI only (no excision): 146</p> <p>Disease positive: 15 (SDDI then histologically confirmed); Disease negative: 176 benign (incl 1 missed <i>in situ</i> melanoma); 4 unknown</p> <p><i>Expert opinion:</i> GPs could refer for specialist opinion or lesions could undergo dermoscopy telemedicine (images reviewed by an expert in dermoscopy and SDDI). Dermoscopy telemedicine was blinded to the GP's diagnosis. Observe for change group, i.e. discharged after dermoscopy: 72 Plus a proportion of those in Excise/refer group will have had expert dx alone but details not given</p> <p>Disease positive: 0; Disease negative: 71 benign; 1 unknown</p> <p>Target condition (Final diagnoses) Melanoma (invasive): 33; Melanoma (in situ): 1 BCC: 6 2 Bowen's disease; 323 benign; 9 unknown</p>
Is the reference standards likely to correctly classify the target condition?	No
Were the reference standard results interpreted without knowledge of the results of the index tests?	No
Could the reference standard, its conduct, or its interpretation have introduced bias?	High risk

B. Concerns regarding applicability

Expert opinion (with no histological confirmation) was not used as a reference standard	No
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear
Are there concerns that the target condition as defined by the reference standard does not match the question?	High

Flow and Timing

A. Risk of Bias	
Flow and timing	<p>Excluded participants: nine lesions with unknown diagnoses, plus BCC and Bowen's excluded from some analyses</p> <p>Time interval to reference test: Not reported; Histopathological and specialist examination occurred according to standard practice</p>
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	No
Were all patients included in the analysis?	No
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	Yes
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	
Could the patient flow have introduced bias?	High risk

Could the selection of patients have introduced bias?	

B. Concerns regarding applicability	
Patient characteristics and setting	Inclusion criteria: All biopsies generated at Pigmented lesion clinic during time period. Setting: Specialist unit (skin cancer/pigmented lesions clinic) Prior testing: Not reported Setting for prior testing: N/A Exclusion criteria: None reported Sample size (patients): No. eligible: 1999 Sample size (lesions): 669 lesions examined by registrar Participant characteristics: None reported Lesion characteristics: None reported
Are the included patients and chosen study setting appropriate?	
Did the study avoid including participants with multiple lesions?	
Are there concerns that the included patients and setting do not match the review question?	

Index Test

Index tests	Visual inspection (VI) No algorithm Method of diagnosis: In person diagnosis Prior test data: N/A in-person diagnosis referred to as 'clinical diagnosis'; no dermoscopy used Diagnostic threshold: Not reported NR; clinical diagnosis Diagnosis based on: Single observer and average data presented; (n= 10 in total) Observer qualifications: Registrars Experience in practice: Low – 6 rotating registrars each with 1-2 years experience Any other detail: Data from same study for consultants and for senior registrars presented in Morton 1998a and Morton 1998b
-------------	--

Visual Inspection - in-person

A. Risk of Bias	
Were the index test results interpreted without knowledge of the results of the reference standard?	
If a threshold was used, was it pre-specified?	
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	
B. Concerns regarding applicability	
Was the test applied and interpreted in a clinically applicable manner?	
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	
Was the test interpretation carried out by an experienced examiner?	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	

Visual inspection - image-based

A. Risk of Bias	
Were the index test results interpreted without knowledge of the results of the reference standard?	
If a threshold was used, was it pre-specified?	
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	
B. Concerns regarding applicability	
Was the test applied and interpreted in a clinically applicable manner?	
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	
Was the test interpretation carried out by an experienced examiner?	
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	

Reference Standard

A. Risk of Bias	
Target condition and reference standard(s)	<p>Reference standard - Histological diagnosis alone</p> <p>Target condition (Final diagnoses) (For full sample of 1999 biopsies)</p> <p>Melanoma (invasive): 102 (82 SSM, 11 nodular melanoma, 4 partially regressed, 2 acral lentiginous, 2 metastatic CM deposits, 1 desmoplastic melanoma); Melanoma (in situ): 24; Lentigo maligna: 2</p> <p>Benign: 1871 benign (breakdown by lesion type not reported)</p>
Is the reference standards likely to correctly classify the target condition?	
Were the reference standard results interpreted without knowledge of the results of the index tests?	
Could the reference standard, its conduct, or its interpretation have introduced bias?	
B. Concerns regarding applicability	
Expert opinion (with no histological confirmation) was not used as a reference standard	
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	
Are there concerns that the target condition as defined by the reference standard does not match the question?	

Flow and Timing

A. Risk of Bias	
Flow and timing	<p>Excluded participants: None reported</p> <p>Time interval to reference test: Not reported</p> <p>Time interval between index test(s): N/A</p>
Was there an appropriate interval between index test and reference standard?	
Did all patients receive the same reference standard?	
Were all patients included in the analysis?	
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	
Could the patient flow have introduced bias?

Scope 2008

Patient Selection

A. Risk of Bias	
Patient Sampling	Study design: Case series Data collection: Retrospective image selection / Prospective interpretation Period of data collection after January 2003 Country Not reported
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	Inclusion criteria: Images of pigmented skin lesions selected from a database of standardised patient images provided by a New Zealand-based teledermatology company (MoleMap). Images were selected on the basis that (1) at least 8 clinically atypical nevi were apparent on the back; (2) most of the lesions on the back and all of the atypical nevi had close-up clinical digital images; (3) 1-year follow-up images (close-up clinical and dermoscopic images) were available to show that lesions considered to be benign were in fact biologically indolent by revealing no change; and (4) the image quality of both the overview and the close-up images were acceptable Setting: New Zealand based teledermatology company; images were sent electronically to participants as a powerpoint file. Prior testing: Not reported Setting for prior testing: Unspecified Exclusion criteria: Poor quality index test image (considered under flow/timing); naevi on any body site except the back Sample size (patients): No. eligible: 12; No. included: 12 Sample size (lesions): No. eligible: 145; No. included: 145 Participant characteristics: None reported Lesion characteristics: None reported
Are the included patients and chosen study setting appropriate?	Unclear
Did the study avoid including participants with multiple lesions?	No
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	<p>Visual inspection (VI) Ugly duckling</p> <p>Method of diagnosis: Clinical photographs</p> <p>Prior test data: No further information used</p> <p>Diagnostic threshold: For each lesion that was deemed as different, the participants had to mark the lesion number on the form, identify it as either completely different or somewhat different from the other moles, give a short qualitative description of how the lesion differs, and report whether they would like to have a biopsy performed on the lesion</p> <p>Diagnosis based on: Average (n=34)</p> <p>Observer qualifications: Four subgroups in terms of clinical expertise: group 1, pigmented lesion experts (n = 8); group 2, dermatologists who were considered non-experts in pigmented lesion evaluation (n = 13); group 3, dermatology nurses (n = 5, including 1 dermatology medical photographer); and group 4, non-clinical medical staff (n = 8).</p> <p>Experience in practice: Mixed experience (low and high experience combined)</p> <p>Other detail: The study was sent electronically to participants as a powerpoint file (Microsoft Corp, Redmond, Washington) that contained the clinical image interface and a word document that contained questionnaire and response forms. The participants were not shown dermoscopic images. However, dermoscopic images of lesions (with a 1-year follow-up dermoscopic image) were available to the investigators to verify that lesions considered benign did not show dermoscopic features suggestive of malignancy, and the 1-year follow-up images confirmed that the lesions were in fact biologically indolent by revealing no change.</p>

Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	
Could the patient flow have introduced bias?	Unclear risk

Patient Selection

A. Risk of Bias

Patient Sampling	<p>Study design: Case control Data collection: Retrospective image selection / Prospective interpretation Period of data collection Just states 1997 Country Italy</p>
Was a consecutive or random sample of patients enrolled?	Unclear
Was a case-control design avoided?	No
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	High risk

B. Concerns regarding applicability	
Patient characteristics and setting	<p>Inclusion criteria: Images of pigmented skin lesions selected from computerised files of the skin cancer clinic.</p> <p>Setting: Training study; images selected from skin cancer clinic</p> <p>Prior testing: Not reported</p> <p>Setting for prior testing: Unspecified</p> <p>Exclusion criteria: None reported</p> <p>Sample size (patients): Not reported</p> <p>Sample size (lesions): No. included: 30PSLs</p> <p>Participant characteristics: None reported</p> <p>Lesion characteristics: None reported</p>
Are the included patients and chosen study setting appropriate?	No
Did the study avoid including participants with multiple lesions?	Unclear
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	<p>Visual inspection (VI) No algorithm</p> <p>Method of diagnosis: Clinical photographs</p> <p>Prior test data: No further information used</p> <p>Other test data: Dermoscopic images presented to observer subsequent to diagnosis using clinical images alone (images were randomised).</p> <p>Diagnostic threshold: Not reported</p> <p>Diagnosis based on: Average; n= 20</p> <p>Observer qualifications: Dermatologist</p> <p>Experience in practice: Not described; 30 dermatologists with “experience in ELM but (with) no formal training” attended a seminar on clinical and ELM diagnosis of PSL; 20 then participated in a test of their diagnostic accuracy. A second session on ELM was then held.</p> <p>Other detail: The observers received 2hrs seminar of the principles of clinical diagnosis of NMLs, BCC, MN and MM. The participants were then invited to undergo an anonymous test of their diagnostic accuracy.</p> <p>Dermoscopy: evaluated in same study; no algorithm</p>

Visual Inspection - in-person

A. Risk of Bias

B. Concerns regarding applicability

Visual inspection - image-based

A. Risk of Bias

Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
If a threshold was used, was it pre-specified?	Unclear
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	Unclear risk

B. Concerns regarding applicability

Was the test applied and interpreted in a clinically applicable manner?	No
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	No
Was the test interpretation carried out by an experienced examiner?	Unclear
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High

Reference Standard

A. Risk of Bias	
Target condition and reference standard(s)	Reference standard Histological diagnosis alone Target condition (Final diagnoses) Melanoma (in situ and invasive, or not reported): 10 BCC: 4 Mild//moderate dysplasia: 3; Seborrheic keratosis: 3; Benign naevus: Melanocytic nevi-7 Other: 1 hemangioma 1 subungual hemorrhage 1 plantar intraepidermal hemorrhage
Is the reference standards likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability	
Expert opinion (with no histological confirmation) was not used as a reference standard	Yes
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Unclear
Are there concerns that the target condition as defined by the reference standard does not match the question?	Unclear

Flow and Timing

A. Risk of Bias	
Flow and timing	Excluded participants: none reported Time interval to reference test: not reported
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	
Could the patient flow have introduced bias?	Unclear risk

Index tests	<p>Visual inspection (VI) No algorithm; Appears to be original clinical diagnosis at time of lesion presentation</p> <p>Method of diagnosis: In person diagnosis Appears to be diagnosis on presentation</p> <p>Prior test data: N/A in-person diagnosis</p> <p>Other test data: Dermoscopic images presented to different observers</p> <p>Diagnostic threshold: Not reported</p> <p>Diagnosis based on: Unclear - for visual inspection appears to be single examiner at time of clinic diagnosis (n=NR); dermoscopic images "scored by three other experienced dermatoscopists" (n=3)</p> <p>Observer qualifications: Not reported; assumed dermatologists - described as experienced dermatoscopists</p> <p>Experience in practice: Unclear for clinic diagnosis; dermatoscopists described as "experienced"</p> <p>Experience with index test: Described as "experienced"</p> <p>Dermoscopy: evaluated in same study by 3 experienced dermatoscopists; 3-point rule; 7-point checklist; ABCD; CASH algorithm (image based)</p>
-------------	---

Visual Inspection - in-person

A. Risk of Bias	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
If a threshold was used, was it pre-specified?	Unclear
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	Unclear risk

B. Concerns regarding applicability	
Was the test applied and interpreted in a clinically applicable manner?	Yes
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	No
Was the test interpretation carried out by an experienced examiner?	Unclear
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High

Visual inspection - image-based

A. Risk of Bias

B. Concerns regarding applicability

Reference Standard

A. Risk of Bias	
Target condition and reference standard(s)	<p>Reference standard Histological diagnosis alone</p> <p>Disease positive: 24; Disease negative: 91</p> <p>Target condition (Final diagnoses) Melanoma (in situ and invasive, or not reported): 24</p> <p>'Benign' diagnoses: 91 melanocytic benign lesions; 37 (32.2%) dermal nevi; 15 (13%) clark's nevi; 14 (12.2%) compound nevi; 13 (11.3%) blue nevi; 6 (5.2%) spitz nevi; 4 (3.5%) congenital melanocytic nevi; 2 (1.7%) junctional nevi</p>
Is the reference standards likely to correctly classify the target condition?	Yes
Were the reference standard results interpreted without knowledge of the results of the index tests?	Unclear
Could the reference standard, its conduct, or its interpretation have introduced bias?	Low risk

B. Concerns regarding applicability	
Expert opinion (with no histological confirmation) was not used as a reference standard	Yes
Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?	Yes
Are there concerns that the target condition as defined by the reference standard does not match the question?	Low concern

Flow and Timing

A. Risk of Bias	
Flow and timing	<p>Excluded participants: none reported</p> <p>Time interval to reference test: not reported</p> <p>Time interval between index test(s): Appear to be consecutively applied</p>
Was there an appropriate interval between index test and reference standard?	Unclear
Did all patients receive the same reference standard?	Yes
Were all patients included in the analysis?	Yes
If the reference standard includes clinical follow-up of borderline/benign appearing lesions, was there a minimum follow-up following application of index test(s) of at least: 3 months for melanoma or cSCC or 6 months for BCC?	
If more than one algorithm was evaluated for the same test, was the interval between application of the different algorithms 1 month or less?	
Could the patient flow have introduced bias?	Unclear risk

Viglizzo 2004

Patient Selection

A. Risk of Bias	
Patient Sampling	Study design: Case series Data collection: Not reported Period of data collection: Not reported Country: Italy
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Unclear
Could the selection of patients have introduced bias?	Unclear risk
B. Concerns regarding applicability	
Patient characteristics and setting	Inclusion criteria: Pigmented skin lesions examined at the Dermoscopy Service and undergoing excision; a modified version of Kenet's risk stratification approach for dermoscopy (Ascierto 2000) was used to select high and very high risk lesions for excision; medium and low risk lesions were excised based on cosmetic or functional reasons. (2x2 data have been extracted only for melanocytic subgroup). Setting: Specialist unit (skin cancer/pigmented lesions clinic) Dermoscopy service at a university department (Department of Endocrinologic and metabolic disease) Prior testing: Clinical suspicion of malignancy without dermatoscopic suspicion Setting for prior testing: Specialist unit (skin cancer/pigmented lesions clinic) Exclusion criteria: None reported Sample size (patients): No. eligible: 349 patients; No. included: not reported Sample size (lesions): No. eligible: 520 lesions; No. included: 79 lesions excised included in the final analysis Participant characteristics: None reported Lesion characteristics: None reported
Are the included patients and chosen study setting appropriate?	No
Did the study avoid including participants with multiple lesions?	Unclear
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	Visual inspection (VI). No algorithm Method of diagnosis: In person diagnosis Prior test data: Unclear Other test data: Dermoscopy undertaken by same clinician(s) subsequent to clinical evaluation Diagnostic threshold: Not reported; correct diagnosis of melanoma Diagnosis based on: Single observer (n=NR; "All dermoscopic evaluations were performed by the same operators") Observer qualifications: Not reported; "each lesion was .. diagnosed clinically and dermoscopically" at the Dermoscopy service Experience in practice: Not described Experience with dermoscopy: Not described; assumed High as diagnosis at 'Dermoscopy service' Dermoscopy: evaluated in same study; no algorithm

Walter 2012

Patient Selection

A. Risk of Bias	
Patient Sampling	Study design: Randomised controlled trial (control group only included) Data collection: Prospective Period of data collection March 2008 to May 2010 Country UK
Was a consecutive or random sample of patients enrolled?	Yes
Was a case-control design avoided?	Yes
Did the study avoid inappropriate exclusions?	Yes
Could the selection of patients have introduced bias?	Low risk

B. Concerns regarding applicability	
Patient characteristics and setting	Inclusion criteria: Adults with any suspicious pigmented skin lesion, i.e. any lesion presented by a patient, or opportunistically seen by a family doctor or practice nurse, that could not immediately be diagnosed as benign and about which the patient could not be reassured. Setting: Primary 15 general practices in eastern England Prior testing: Clinical suspicion of malignancy without dermatoscopic suspicion Setting for prior testing: Primary Exclusion criteria: Those unable to give informed consent or considered inappropriate to include by their family doctor. Sample size (patients): No. eligible: 1297; No. included: 1293 Sample size (lesions): No. eligible: 1580; No. included: 1583 Participant characteristics: Mean age: 44.6y (SD 16.8). Male: 465 (36%). Ethnicity: White 1214 (93.9%); Mixed 45 (3.5%); Missing: 34 (2.6%) Lesion characteristics. Lesion thickness ≤ 1 mm: in 'more than half' of MM
Are the included patients and chosen study setting appropriate?	Yes
Did the study avoid including participants with multiple lesions?	No
Are there concerns that the included patients and setting do not match the review question?	High

Index Test

Index tests	Visual inspection (VI) Glasgow/MacKie revised seven-point checklist (MacKie 1990) Method of diagnosis: In person diagnosis Prior test data: N/A Diagnostic threshold: Not reported Diagnosis based on: Single observer (n=30) Observer qualifications: 28 GPs and 2 nurse practitioners recruited as 'lead clinicians' (2 per practice); appears though they conducted all skin examinations. Excluded GPs with known dermatological expertise, e.g. current hospital practitioners, clinical assistants in dermatology, and GPs with a special interest in dermatology Experience in practice: Mixed GP experience - median of 15 years experience (range 4 to 27yrs); assumed low experience with pigmented skin lesions- seven had undergone some training in dermatology, three had a short dermatology training post, three were on clinical attachment to an out-patient clinic, and one was unspecified
-------------	---

Visual Inspection - in-person

A. Risk of Bias	
Were the index test results interpreted without knowledge of the results of the reference standard?	Yes
If a threshold was used, was it pre-specified?	Yes
For studies reporting the accuracy of multiple diagnostic thresholds, was each threshold or algorithm interpreted without knowledge of the results of the others?	
Could the conduct or interpretation of the index test have introduced bias?	Low risk
B. Concerns regarding applicability	
Was the test applied and interpreted in a clinically applicable manner?	Yes
Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?	Yes
Was the test interpretation carried out by an experienced examiner?	No
Are there concerns that the index test, its conduct, or interpretation differ from the review question?	High

Visual inspection - image-based

Footnotes

ABCD(E) - asymmetry, border, colour, differential structures (enlargement); AK - actinic keratosis; AMN – atypical melanocytic naevi; BCC - basal cell carcinoma; BD – Bowen’s disease; BN – benign naevi; BPC – between person comparison (of tests); CAD – computer assisted diagnosis; CCS – case control study; CD – compact disc; CM – cutaneous melanoma; CMM - cutaneous malignant melanoma; CS – case series; CSCC – cutaneous squamous cell carcinoma; DF – dermatofibroma; Dx – diagnosis; ELM – epiluminescence microscopy; FPs - false positives; FU – follow-up ; GP – general practitioner; H&E – haematoxylin and eosin stain; LPLK – lichen planus-like keratosis; LS – lentigo simplex; MM – malignant melanoma; MiS – melanoma in situ (or lentigo maligna); MN – melanocytic naevi; MSDSLA - multispectral digital skin lesion analysis device; N/A – not applicable; NC – non comparative; NMLs – non melanocytic lesions; NR – not reported; P – prospective; PCPs – primary care providers; PLC – pigmented lesion clinic; PSL – pigmented skin lesion; R –retrospective; RCM – reflectance confocal microscopy; RCT – randomised controlled trial; SCC - squamous cell carcinoma; SD – standard deviation; SDDI - short-term sequential digital dermoscopy imaging; SK – seborrheic keratosis; SN – Spitz nevi; SSM – superficial spreading melanoma; SVS – support vector system; VI – visual inspection; WPC – within person comparison (of tests).

Characteristics of excluded studies

Abbasi 2004

Reason for exclusion	EXCLUDE not a primary study <i>systematic review</i>
----------------------	---

Aldridge 2011

Reason for exclusion	EXCLUDE on test observer <i>medical students and lay persons</i>
----------------------	---

Aldridge 2011a

Reason for exclusion	EXCLUDE on test observer
----------------------	--------------------------

Aldridge 2013

Reason for exclusion	EXCLUDE on 2x2 data <i>not test accuracy study</i>
----------------------	---

Alendar 2009

Reason for exclusion	EXCLUDE on reference standard <i>only 7 reported verified histologically</i>
----------------------	---

Argenziano 1999

Reason for exclusion	EXCLUDE on study population <i>Only includes melanoma</i>
----------------------	--

Argenziano 2003

Reason for exclusion	EXCLUDE on 2x2 data <i>Table V gives se/sp data for 108 lesions but can't derive the number of melanoma for this subset of the original 128</i> Authors contacted 10/5/16; 24/6/16
----------------------	--

Argenziano 2012

Reason for exclusion	EXCLUDE on reference standard <i>no follow-up of test negatives</i>
----------------------	--

Argenziano 2014

Reason for exclusion	EXCLUDE on 2x2 data
----------------------	---------------------

Ascierto 2003

Reason for exclusion	EXCLUDE not a primary study
----------------------	-----------------------------

Badertscher 2015

Reason for exclusion	EXCLUDE on 2x2 data
----------------------	---------------------

Bafounta 2001

Reason for exclusion	EXCLUDE not a primary study <i>systematic review</i>
----------------------	---

Banky 2005

Reason for exclusion	EXCLUDE on target condition EXCLUDE on index test
----------------------	--

Basarab 1996

Reason for exclusion	EXCLUDE on study population <i>not all suspected of skin cancer</i> EXCLUDE on 2x2 data
----------------------	---

Bauer 2000

Reason for exclusion	EXCLUDE on index test <i>Does not provide 2x2 data for visual inspection alone</i>
----------------------	---

Bauer 2005

Reason for exclusion	EXCLUDE on index test <i>follow-up/monitoring study</i>
----------------------	--

Becker 1954

Reason for exclusion	EXCLUDE not a primary study
----------------------	-----------------------------

Benelli 2000

Reason for exclusion	EXCLUDE on 2x2 data <i>only inter-rater reliability data given (n=25); authors have published much larger evaluations of 7FFM and ABCD</i>
----------------------	---

Blum 2004

Reason for exclusion	EXCLUDE not a primary study <i>comment paper</i>
----------------------	---

Blum 2004a

Reason for exclusion	EXCLUDE not a primary study <i>letter</i> EXCLUDE <i>Letter only; limited data presented - evaluates '3-colour' rule as developed By Mackie 1992 (excluded as assessment of individual lesion features only)</i>
----------------------	--

Blum 2004b

----------------------	--

Cornell 2015

Reason for exclusion	EXCLUDE on test observer
----------------------	--------------------------

Cox 2008

Reason for exclusion	EXCLUDE on reference standard <i>Se and sp estimates for diagnosis of melanoma for both the seven-point checklist and the revised (10-point) checklist; reference standard not reported for any of the 381 TWR referrals for melanoma</i> EXCLUDE but contact authors <i>Author contacted 10/05/16; co-author contacted 24-6-16</i>
----------------------	--

De Giorgi 2011

Reason for exclusion	EXCLUDE Duplicate publication Study appears to use same lesions as Carli 2003b (included study). Both studies have the same numbers of melanomas and benign nevi and have common co-authors (De Giorgi 2011 in particular). Although not explicit, the De Giorgi 2011 paper appears to have used the same lesions and study design but with different observers. The original Carli 2003 paper reported using 8 expert observers while the later paper recruited 8 dermatologists who had undergone a dermoscopy training course but who reported no experience in assessing pigmented skin lesions.
----------------------	--

DeCoste 1993

Reason for exclusion	EXCLUDE on 2x2 data <i>Not given the total number of D+/D- or total number of lesions included. Just given the sensitivity/specificity values</i>
----------------------	--

Di Carlo 2014

Reason for exclusion	EXCLUDE on index test. Videothermography not relevant for the review and there is no 2x2 data for dermoscopy EXCLUDE if derivation study. Only includes AK and BCC; no 2x2 for dermoscopy
----------------------	---

Di Chiacchio 2010

Reason for exclusion	EXCLUDE not a primary study <i>clinical trial protocol</i>
----------------------	---

Walter 2013

Reason for exclusion	EXCLUDE on reference standard <i>Final diagnosis reached by histology or expert opinion; no FU of non-excised lesions reported in this paper. The Walter 2012 trial report does report follow-up for enough benign lesions for control arm (weighted 7PCL) data to be included. Authors contacted and confirmed calculations (02/03/16).</i>
----------------------	---

Warshaw 2009

Reason for exclusion	EXCLUDE on 2x2 data <i>Study presents diagnostic accuracy of teledermatology and clinic diagnosis in comparison to histopathology; in order to include in our review, data would need to be presented as a 2x2 contingency table, either per type of malignancy e.g. tele-dx classification of melanoma vs not melanoma against histological diagnosis of melanoma/not melanoma, or with malignant diagnoses grouped together, ie tele-dx of malignancy vs not malignant against same histological breakdown.</i> EXCLUDE but contact authors <i>Authors contacted: the 2x2 table the Cochrane researchers want to create is not possible for our results, because sensitivity and PPV are based on different sample sizes. This can be seen in Table 2 of the paper which actually adds up to 11870 skin lesions across, as for each histological diagnosis of interest the first lesion with such a histological diagnosis was considered per patient. Hence, a patient might appear several times across the columns. Table 1 adds up to 8585 skin lesions – the first skin lesion in the data set per patient with a clinical diagnosis.</i>

Summary of results tables

1 Summary of findings table

Question:	What is the diagnostic accuracy of visual inspection for the detection of cutaneous invasive melanoma and atypical intraepidermal melanocytic variants in adults?		
Population:	Adults with lesions suspicious for melanoma, including: <ul style="list-style-type: none"> • those with limited prior testing (presenting in primary, community or private dermatology settings), and • referred populations (presenting in secondary care or specialist skin cancer clinics). 		
Index test:	Visual inspection with or without the use of any established algorithms or checklist to aid diagnosis, including: <ul style="list-style-type: none"> • in-person evaluations (face-to-face diagnosis), and • image-based evaluations (diagnosis based on assessment of a clinical image). 		
Target condition:	Cutaneous invasive melanoma and atypical intraepidermal melanocytic variants		
Reference standard:	Histology with or without long term follow-up		
Action:	If accurate, positive results ensure melanoma lesions are not missed but are appropriately referred and excised and those with negative results can be safely reassured and discharged.		
	Number of studies	Total lesions	Total cases
Quantity of evidence	49*	34351	2499
Limitations			
Risk of bias:	Potential risk for patient selection from case control design (6), inappropriate exclusion criteria (7) or lack of detail (27/49). All index test interpretation was blinded to reference standard diagnosis. Index test thresholds not clearly pre-specified (22/28 in-person evaluations; 13/16 image-based). Low risk for reference standard (42/49); high concern from use of expert diagnosis (6). Blinding of reference standard to visual inspection diagnosis not reported in any study. High risk for participant flow due to differential verification (11), and exclusions following recruitment (15); timing of tests was not mentioned in 37.		
Applicability of evidence to question:	Participants restricted to those with melanocytic lesions only (10), or to those with histopathology results (37) and included multiple lesions per participant (14). No description of diagnostic thresholds (24 in-person; 13 image-based) or reporting of average or consensus diagnoses (7 in-person; 13 image-based). Clinical images interpreted blinded to clinical information (11/16). Little information given concerning the expertise of the histopathologist (40/49).		
FINDINGS:			

Question:	What is the diagnostic accuracy of visual inspection for the detection of cutaneous invasive melanoma and atypical intraepidermal melanocytic variants in adults?					
Thirty-seven studies (providing 39 datasets) reporting accuracy data for the primary target condition were separated <i>a priori</i> into in-person (n=28) and image-based (n=11) evaluations. Subsequent analysis confirmed differences in accuracy according to the different approaches to diagnosis (P<0.001). Attempts to analyse studies by degree of prior testing were hampered by a lack of relevant information provided in the study publications and by the inclusion of lesions selected for biopsy or excision. Of the 28 in-person evaluations, only 17 could be clearly placed on the clinical pathway, and 11 were considered not to have provided sufficient information to allow the pathway to be identified (coded 'unclear' on pathway). The findings presented are based on results for in-person evaluations that could be clearly placed on the clinical pathway.						
Test:	In-person visual inspection using any or no algorithm at any threshold

Footnotes

*37 of the 49 included studies (reporting on 39 cohorts of lesions) provide data for the primary target condition (defined as detection of cutaneous invasive melanoma and atypical intraepidermal melanocytic variants) and are the main focus of this 'Summary of findings' table; the summary of methodological quality is based on the full sample of 49 studies.

** Number of true positives (TP), false positives (FP), false negatives (FN), true negatives (TN) for a hypothetical cohort of 1000 lesions have been estimated at the median and interquartile ranges of prevalence (25th and 75th percentiles), at average sensitivity and specificity and using the lower and upper limits of the 95% confidence intervals, denoted in square brackets [lower limit; upper limit].

Differences in-person and image-based								
Detection of invasive melanoma alone								
In-person	7	6857 (208)	62.4 (17.6, 222)	86% (68, 94)	91% (81, 96)	4.21 (0.62, 28.6)	0.13	0.27
Image-based	5	599 (150)	14.8 (3.56, 61.9)	76% (50, 91)	83% (62, 93)			
Detection of any skin lesion requiring excision								
In-person	7	8091 (2187)	20.5 (7.11, 59.3)	81% (68, 90)	81% (56, 93)	1.70 (0.24, 12.3)	0.55	0.87
Image-based	3	547 (138)	11.9 (2.22, 65.3)	75% (49, 90)	79% (38, 96)			

Footnotes

* Likelihood ratio test assessing differences in both accuracy and threshold

7 Results for studies reporting data for more than one definition of the target condition

Study author	Detection of invasive melanoma			Detection of invasive melanoma or atypical intraepidermal melanocytic variants			Detection of any lesion requiring excision		
	Dis/ non-dis (prev)*	Sensitivity (95% CIs)	Specificity (95% CIs)	Dis/ non-dis (prev)*	Sensitivity (95% CIs)	Specificity (95% CIs)	Dis/ non-dis (prev)*	Sensitivity (95% CIs)	Specificity (95% CIs)
In-person									
Ek 2005	-	-	-	23 / 2559; 1%	48% (27, 69)	99% (99, 99)	1754 / 828; 68%	98% (97, 98)	13% (11, 15)
McGovern 1992	6 / 186; 3%	100% (54, 100)	89% (83, 93)	11 / 181; 6%	73% (39, 94)	88% (83, 93)	15 / 177; 8%	73% (45, 92)	88% (82, 93)
Stanganelli 2000	-	-	-	55 / 3317; 2%	67% (53, 79)	99% (99, 100)	98 / 3274; 3%	71% (61, 80)	99% (99, 99)
Steiner 1987	-	-	-	73 / 245; 23%	59% (47, 70)	87% (83, 91)	93 / 225; 29%	67% (56, 76)	86% (81, 90)
Walter 2012	16 / 757; 2%	94% (70, 100)	80% (77, 83)	18 / 755; 2%	94% (73, 100)	80% (77, 83)	22 / 751; 3%	82% (60, 95)	80% (77, 83)
Image-based									
Carli 2002b	-	-	-	10 / 43; 19%	80% (44, 97)	84% (69, 93)	20 / 34; 37%	80% (56, 94)	74% (56, 87)
Rosendahl 2011	-	-	-	29 / 434; 6%	21% (08, 40)	97% (95, 98)	104 / 359; 22%	76% (67, 84)	85% (81, 88)
Stanganelli 1998	-	-	-	10 / 20; 33%	40% (12, 74)	75% (51, 91)	14 / 16; 47%	64% (35, 87)	75% (48, 93)

Footnotes

*Number of diseased / number of non-diseased (prevalence of disease), for each definition of the target condition

22. Sentinel lymph node biopsy ± high frequency ultrasound	15 to 20

2 Glossary of terms

Term	Definition
Atypical intraepidermal melanocytic variant	Unusual area of darker pigmentation contained within the epidermis that may progress to an invasive melanoma; includes melanoma <i>in situ</i> and lentigo maligna
Atypical naevi	Unusual looking but noncancerous mole or area of darker pigmentation of the skin
BRAF V600 mutation	BRAF is a human gene that makes a protein called B-Raf which is involved in the control of cell growth. BRAF mutations (damaged DNA) occur in around 40% of melanomas, which can then be treated with particular drugs.
BRAF inhibitors	Therapeutic agents which inhibit the serine-threonine protein kinase BRAF mutated metastatic melanoma.
Breslow thickness	A scale for measuring the thickness of melanomas by the pathologist using a microscope, measured in mm from the top layer of skin to the bottom of the tumour.
Congenital naevi	A type of mole found on infants at birth

#164d Visual inspection for the diagnosis of cutaneous melanoma in adults

Term	Definition
Dermoscopy	Whereby a handheld microscope is used to allow more detailed, magnified, examination of the skin compared to examination by the naked eye alone
False negative	An individual who is truly positive for a disease, but whom a diagnostic test classifies them as disease-free.
False positive	An individual who is truly disease-free, but whom a diagnostic test classifies them as having the disease.
Histopathology/Histology	The study of tissue, usually obtained by biopsy or excision, for example under a microscope.
Incidence	The number of new cases of a disease in a given time period.
Index test	A diagnostic test under evaluation in a primary study
Lentigo maligna	Unusual area of darker pigmentation contained within the epidermis which includes malignant cells but with no invasive growth. May progress to an invasive melanoma
Lymph node	Lymph nodes filter the lymphatic fluid (clear fluid containing white blood cells) that travels around the body to help fight disease; they are located throughout the body often in clusters (nodal basins).
Melanocytic naevus	An area of skin with darker pigmentation (or melanocytes) also referred to as 'moles'
Meta-analysis	A form of statistical analysis used to synthesise results from a collection of individual studies.
Metastases/metastatic disease	Spread of cancer away from the primary site to somewhere else through the bloodstream or the lymphatic system.
Micrometastases	Micrometastases are metastases so small that they can only be seen under a microscope.
Mitotic rate	Microscopic evaluation of number of cells actively dividing in a tumour.
Morbidity	Detrimental effects on health.
Mortality	Either (1) the condition of being subject to death; or (2) the death rate, which reflects the number of deaths per unit of population in relation to any specific region, age group, disease, treatment or other classification, usually expressed as deaths per 100, 1000, 10,000 or 100,000 people.
Multidisciplinary team	A team with members from different healthcare professions and specialties (e.g. urology, oncology, pathology, radiology, and nursing). Cancer care in the National Health Service (NHS) uses this system to ensure that all relevant health professionals are engaged to discuss the best possible care for that patient.
Prevalence	The proportion of a population found to have a condition.
Prognostic factors/indicators	Specific characteristics of a cancer or the person who has it which might affect the patient's prognosis.
Receiver operating characteristic (ROC) plot	A plot of the sensitivity and 1 minus the specificity of a test at the different possible thresholds for test positivity; represents the diagnostic capability of a test with a range of binary test results
Receiver operating characteristic (ROC) analysis	The analysis of a ROC plot of a test to select an optimal threshold for test positivity
Recurrence	Recurrence is when new cancer cells are detected following treatment. This can occur either at the site of the original tumour or at other sites in the body.
Reference Standard	A test or combination of tests used to establish the final or 'true' diagnosis of a patient in an evaluation of a diagnostic test
Reflectance confocal microscopy (RCM)	A microscopic technique using infrared light (either in a handheld device or a static unit) that can create images of the deeper layers of the skin
Sensitivity	In this context the term is used to mean the proportion of individuals with a disease who have that disease correctly identified by the study test
Specificity	The proportion of individuals without the disease of interest (in this case with benign skin lesions) who have that absence of disease correctly identified by the study test
Staging	Clinical description of the size and spread of a patient's tumour, fitting into internationally agreed categories.

Term	Definition
Subclinical (disease)	Disease that is usually asymptomatic and not easily observable, e.g. by clinical or physical examination.
Systemic treatment	Treatment, usually given by mouth or by injection, that reaches and affects cancer cells throughout the body rather than targeting one specific area.

3 Table of acronyms and abbreviations used

Acronym	Definition
3PCL	three point checklist
7FFM	seven features for melanoma
7PCL	seven point checklist
ABCD(E)	asymmetry, border, colour, differential structures (enlargement)
AHM	amelanotic or hypomelanotic melanoma
AK	actinic keratosis
AMN	atypical melanocytic naevi
AUC	area under the curve
BCC	basal cell carcinoma
BD	Bowen's disease
BN	benign naevi
BNM	benign non-melanocytic
BPC	between person comparison (of tests)
CAD	computer assisted diagnosis
CCS	case control study
CD	compact disc
CM	cutaneous melanoma
CMM	cutaneous malignant melanoma
CS	case series
CSCC	cutaneous squamous cell carcinoma
D-	disease negative
D+	disease positive
DF	dermatofibroma
Dx	diagnosis
ELM	epiluminescence microscopy
FN	false negative
FP	false positive
FU	Follow- up
GP	general practitioner
H&E	haematoxylin and eosin stain
LPLK	lichen planus- like keratosis
LS	lentigo simplex
MiS	melanoma in situ (or lentigo maligna)
MM	malignant melanoma
MN	melanocytic naevi
MSDSLA	multispectral digital skin lesion analysis device

Acronym	Definition
N/A	not applicable
NC	non comparative
NMLs	non melanocytic lesions
NPV	negative predictive value
NR	not reported
P	prospective
PCPs	primary care providers
PLC	pigmented lesion clinic
PPV	positive predictive value
PSL	pigmented skin lesion
R	retrospective
RCM	reflectance confocal microscopy
RCT	randomised controlled trial
SCC	squamous cell carcinoma
SD	standard deviation
SDDI	Short term sequential digital dermoscopy imaging
se	sensitivity
sp	specificity
SK	seborrhoeic keratosis
SN	Spitz nevi
SSM	superficial spreading melanoma
SVS	support vector system
TD	teledermatology
TN	true negative
TWR	two week rule
VI	visual inspection
WPC	within person comparison (of tests)
WPC-algs	within person comparison (of algorithms)

4 Content of algorithms used to assist melanoma diagnosis by visual inspection alone

<p>ABCD (Friedman 1985; Rigel 1993; Pehamberger 1993)</p> <p>ABCDE (Carli 1994; Cristofolini 1994; Thomas 1998; Benelli 1999; Benelli 2001; Abbasi 2004)</p> <p>BCD (McGovern 1992)</p>	<p>Seven-point checklist (Mackie 1985; Mackie 1990; Keefe 1990)</p>	<p>Seven-point checklist (revised) (Mackie 1990; Healsmith 1994)</p>
<p>A – asymmetry</p> <ul style="list-style-type: none"> • variable centripetal growth of melanocytes (Friedman 1985) • “geometrical asymmetry in two axes of the tumour” (Thomas 1998; Benelli 1999; Benelli 2001) • “one half does not match the other half” (McGovern 1992); not separately scored in study “because we believed that asymmetry and border 	<ul style="list-style-type: none"> • sensory change (greater awareness of the lesion or mild itch); • diameter of ≥ 1 cm; • growth of the lesion; • an irregular edge; • irregular pigment with different shades of brown and black in the lesion; 	<p>Mackie 1990, Mackie 1991, and Healsmith 1994 describe the revised criteria as:</p> <p>Major signs</p> <ul style="list-style-type: none"> • Change in size • Change in shape • Change in colour <p>Minor signs</p> <ul style="list-style-type: none"> • Inflammation • Crusting or bleeding

<p>irregularity were linked”</p> <p>B - irregular borders</p> <ul style="list-style-type: none"> • irregular shape with notching or scalloping of border (Friedman 1985) • “edges are ragged, notched, or blurred (McGovern 1992) • “irregular and notched” (Cristofolini 1994) • “unsharp or ill-defined or angular” (Thomas 1998) • “ragged or indented” (Benelli 1999, Benelli 2001) <p>C - colour</p> <ul style="list-style-type: none"> • variable pigmentation, multiple colours; various of hues of brown, also black, blue, red and white (Friedman 1985) • “pigmentation is not uniform; shades of tan, brown and black are present with dashes of red, white, or blue” (McGovern 1992) • “mottled-haphazard display” (Cristofolini 1994) • “presence of at least two different colours within the lesion (with the exception of the usual symmetrical darkening of the lesion in its center)” (Thomas 1998; Benelli 2001) • “multiple colours” (Abbasi 2004) <p>D - diameter equal or superior to 6mm</p> <ul style="list-style-type: none"> • all studies agree <p>E - evolution</p> <ul style="list-style-type: none"> • “changes in pigmentation” (Cristofolini 1994) • “enlargement of the surface (and not in height) of the lesion; anamnestic criterion based on the patient’s description of the natural history of the lesion” (Thomas 1998) • “elevation, enlargement or change in the color of the lesion” (Benelli 1999; Benelli 2001) • “evolving (with respect to size, shape, shades of colour, surface features, or symptoms)” (Abbasi 2004) <p>McGovern 1992 describes 7 characteristics as: “increasing size, variegation, inflammation, irregular outline, greater than 1cm diameter, itch, bleeding”</p> <p>These are expanded on in MacKie 1990, who describes the original (1985) criteria as:</p> <ul style="list-style-type: none"> • sensory change, often described as a greater awareness of the lesion but also as a mild itch; • diameter of 1 cm or greater; • growth of the lesion; • an irregular edge; • irregular pigment with different shades of brown and black in the lesion; • inflammation (a reddish tinge within the lesion); and • crusting, oozing, or bleeding. 	<ul style="list-style-type: none"> • inflammation • crusting, oozing, or bleeding. <p>Presence of 3 or more suggestive of melanoma</p>	<ul style="list-style-type: none"> • Sensory change • Diameter ≥ 7 mm <p>“a patient with a pigmented lesion with any one of the major signs should be considered for referral and that the presence of any of the minor signs should be a further stimulus to referral.” (MacKie 1990)</p>
--	--	--

<ul style="list-style-type: none"> • ≥ 3 criteria should prompt referral (MacKie 1990) 		

5 Proposed sources of heterogeneity

i. Population characteristics

- general versus higher risk populations
- patient population: primary/secondary/specialist unit
- lesion suspicion: general suspicion/atypical/equivocal/NR
- lesion type: any pigmented; melanocytic
- inclusion of multiple lesions per participant
- ethnicity

ii. Index test characteristics

- the nature of and definition of criteria for test positivity
- observer experience with the index test
- approaches to lesion preparation (e.g. the use of oil or antiseptic gel for dermoscopy)

iii. Reference standard characteristics

- reference standard used
- whether histology-reporting meets pathology-reporting guidelines
- use of excisional versus diagnostic biopsy
- whether two independent dermatopathologists reviewed histological diagnosis

iv. Study quality

- consecutive or random sample of participants recruited
- index test interpreted blinded to the reference standard result
- index test interpreted blinded to the result of any other index test
- presence of partial or differential verification bias (whereby only a sample of those subject to the index test are verified by the reference test or by the same reference test with selection dependent on the index test result)
- use of an adequate reference standard
- overall risk of bias

8 Quality assessment (based on QUADAS-2)

The QUADAS-2 checklist ([Whiting 2011](#)) was tailored to the review topic as follows below.

Patient selection domain (1)

Selective recruitment of study participants can be a key influence on test accuracy. In general terms, all participants eligible to undergo a test should be included in a study, allowing for the intended use of that test within the context of the study. We considered studies that separately sampled malignant and benign lesions to have used a case-control design; and those that supplemented a series of suspicious lesions with additional malignant or benign lesions to be at unclear risk of bias

In terms of exclusions, we considered studies that excluded particular lesion types (e.g. lentigo maligna), particular lesion sites, or that excluded lesions on the basis of image quality or lack of observer agreement (e.g. on histopathology) to be at high risk of bias.

In judging the applicability of patient populations to the review question, we considered restriction to particular lesion populations, such as melanocytic, nodular, high risk or restrictions by size to be of high concern for applicability.

Given that diagnosis of skin cancer is primarily lesion-based, there is the potential for study participants with multiple lesions to contribute disproportionately to estimates of test accuracy, especially if they are at particular risk of having skin cancer. We considered studies that include a high number of lesions in relation to the number of study to be less representative than studies conducted in a more general population participants (i.e. if the difference between the number of included lesions and number of included participants is greater than 5%).

Index test domain (2)

Given the potential for subjective differences in test interpretation for melanoma, the interpretation of the index test blinded to the result of the reference standard is a key means of reducing bias. For prospective studies and retrospective studies that used the original index test interpretation, the diagnosis will by nature be interpreted and recorded before the result of the reference standard is known; however, studies using previously acquired images could be particularly susceptible to information bias. For these studies to be at low risk of bias, we required a clear indication that observers were unaware of the reference standard diagnosis at time of test interpretation. An item was also added to assess the presence of blinding between interpretations of different algorithms, however this item was not included in the overall assessment of risk of bias.

Pre-specification of the index test threshold was considered present if the study clearly reported that the threshold used was not data driven, i.e. was not based on study results. Studies that did not clearly describe the threshold used but that required clinicians to record a diagnosis or management decision for a lesion were considered to be unclear on this criterion. Studies reporting accuracy for multiple numeric thresholds, where ROC analysis was used to select the threshold, or that reported accuracy for the presence of independently significant lesion characteristics with no separate test set of lesions were considered at high risk of bias.

In terms of applicability of the index test to the review question, we required the test to be applied and interpreted as it would be in a clinical practice setting, i.e. in-person or face-to-face with the patient, and by a single observer as opposed to a consensus decision or average across multiple observers. Image-based studies were considered to be high concern, although RCM image interpretations where the observer was also supplied with a clinical or dermoscopic image of the lesion

along with some patient characteristics were considered 'unclear'.

Despite the often subjective nature of test interpretation, it is also important for study authors to outline the particular lesion characteristics that were considered to be indicative for melanoma, particularly where established algorithms or checklists were not used. Studies were considered of low concern if the threshold used was established in a prior study or sufficient threshold details were presented to allow replication.

The experience of the examiner will also impact on the applicability of study results. We required studies to describe the test interpreter as 'experienced' or 'expert' in RCM to have low concern about applicability.

Reference standard domain (3)

In an ideal study, consecutively recruited participants should all undergo incisional or excisional biopsy of the skin lesion regardless of level of clinical suspicion of melanoma. In reality, both partial and differential verification bias are likely. Partial verification bias may occur where histology is the only reference standard used, and only those participants with a certain degree of suspicion of malignancy based on the result of the index test undergo verification, the others either being excluded from the study or defined as being disease-negative without further assessment or follow-up, as discussed above.

Differential verification bias will be present where other reference standards are used in addition to histological verification of suspicious lesions. A typical example of verification bias in skin cancer occurs when investigators do not biopsy people with benign-appearing lesions but instead follow them up for a period of time to determine whether any malignancy subsequently develops (these would be false-negatives on the index test). We defined an 'adequate' reference standard as: all disease-positive individuals having a histological reference standard either at the time of application of the index test or after a period of clinical follow-up; and at least 80% of disease-negative participants have received a histological diagnosis, with up to 20% undergoing at least three months' follow-up of benign-appearing lesions.

A further challenge is the potential for incorporation bias, i.e. where the result of the index test is used to help determine the reference standard diagnosis. It is normal practice for the clinical diagnosis (usually by visual inspection or dermoscopy) to be included on pathology request forms and for the histopathologist to use this diagnosis to help with the pathology interpretation. Although inclusion of such clinical information on the histopathology request form is theoretically a form of incorporation bias, blinded interpretation of the histopathology reference standard is not normal practice, and enforcement of such conditions would significantly limit the generalisability of the study results. For studies evaluating RCM, this item was divided into two questions, firstly whether the reference standard was blinded to the index test result (RCM), and secondly whether it was blinded to the clinical diagnosis. Only the response to the first part (i.e. blinding to RCM) was included in our overall assessment of risk of bias for the reference standard domain.

In judging the applicability of the reference standard to our review question, scored studies as high concern around applicability if they used expert diagnosis (with no follow-up) as a reference standard in any patient, or did not report histology interpretation by a dermatopathologist.

Flow and timing domain (4)

In the ideal study, the diagnosis based on the index test and reference standard should be made consecutively or as near to each other in time as possible to avoid changes in lesion over time. For lesions with a histological reference standard, we have defined a one-month period as an appropriate interval between application of the index test and the reference standard. For studies using clinical follow-up, a minimum three-month follow-up period has been defined as at low risk of bias for detecting false-negatives. This interval was chosen based on a study showing that most false-negative melanomas will be diagnosed within three months of the initial negative index test although a small number will be diagnosed up to 12 months subsequently ([Altamura 2008](#)).

In assessing whether all patients were included in the analysis, we considered studies at high risk of bias if participants were excluded following recruitment.

Comparative domain

A comparative domain was added to the QUADAS-2 checklist for studies comparing the accuracy of RCM and dermoscopy. Items were included to assess the presence blinding of interpretation between tests, and to specify a maximum of one month interval between application of index tests, as intervals greater than these may be accompanied by changes in tumour characteristics. As it would not be normal practice for RCM to be interpreted blinded to the clinical or dermoscopic diagnosis, the scoring of this item did not contribute to our overall assessment of risk of bias. We also considered whether both tests were applied and interpreted in a clinically applicable manner.

The following tables use text that was originally published in the QUADAS-2 tool by Whiting and colleagues ([Whiting 2011](#)).

Item	Response (delete as required)
PARTICIPANT SELECTION (1) RISK OF BIAS	
1) Was a consecutive or random sample of participants or images enrolled?	Yes – if paper states consecutive or random No – if paper describes other method of sampling Unclear – if participant sampling not described

Item	Response (delete as required)
PARTICIPANT SELECTION (1) RISK OF BIAS	
2) Was a case-control design avoided?	<p>Yes – if consecutive or random or case-control design clearly not used</p> <p>No – if study described as case-control or describes sampling specific numbers of participants with particular diagnoses</p> <p>Unclear – if not described</p>
3) Did the study avoid inappropriate exclusions, e.g. <ul style="list-style-type: none"> • 'difficult to diagnose' lesions not excluded • lesions not excluded on basis of disagreement between evaluators 	<p>Yes if inappropriate exclusions were avoided</p> <p>No – if lesions were excluded that might affect test accuracy, e.g. 'difficult to diagnose' lesions, or where disagreement between evaluators was observed</p> <p>Unclear – if not clearly reported but there is suspicion that difficult to diagnose lesions may have been excluded</p>
4) For between-person comparative studies only (i.e. allocating different tests to different study participants): <ul style="list-style-type: none"> • A) were the same participant selection criteria used for those allocated to each test? • B) was the potential for biased allocation between tests avoided through adequate generation of a randomised sequence? • C) was the potential for biased allocation between tests avoided through concealment of allocation prior to assignment? 	<p>For A)</p> <ul style="list-style-type: none"> • Yes – if same selection criteria were used for each index test, No – if different selection criteria were used for each index test, Unclear – if selection criteria per test were not described, N/A – if only 1 index test was evaluated or all participants received all tests <p>For B)</p> <ul style="list-style-type: none"> • Yes – if adequate randomisation procedures are described, No – if inadequate randomisation procedures are described, Unclear – if the method of allocation to groups is not described (a description of 'random' or 'randomised' is insufficient), N/A – if only 1 index test was evaluated or all participants received all tests <p>For C)</p> <ul style="list-style-type: none"> • Yes – if appropriate methods of allocation concealment are described, No – if appropriate methods of allocation concealment are not described, Unclear – if the method of allocation concealment is not described (sufficient detail to allow a definite judgement is required), N/A – if only 1 index test was evaluated
Could the selection of participants have introduced bias? <u>For non-comparative and within-person-comparative studies</u> <ol style="list-style-type: none"> 1. If answers to all of questions 1), 2), and 3) 'Yes': 2. If answers to any 1 of questions 1), 2), or 3) 'No': 3. If answers to any 1 of questions 1), 2), or 3) 'Unclear': <u>For between-person comparative studies</u> <ol style="list-style-type: none"> 1. If answers to all of questions 1), 2), 3), and 4) 'Yes': 2. If answers to any 1 of questions 1), 2), 3), or 4) 'No': 3. If answers to any 1 of questions 1), 2), 3), or 4) 'Unclear': 	<p><u>For non-comparative and within-person-comparative studies</u></p> <ol style="list-style-type: none"> 1. Risk is low 2. Risk is high 3. Risk unclear <p><u>For between-person comparative studies</u></p> <ol style="list-style-type: none"> 1. Risk is low 2. Risk is high 3. Risk unclear
PARTICIPANT SELECTION (1) CONCERNS REGARDING APPLICABILITY	

Item	Response (delete as required)
PARTICIPANT SELECTION (1) RISK OF BIAS	
<p>1) Are the included participants and chosen study setting appropriate to answer the review question, i.e. are the study results generalisable?</p> <ul style="list-style-type: none"> This item is not asking whether exclusion of certain participant groups might bias the study's results (as in Risk of Bias above), but is asking whether the chosen study participants and setting are appropriate to answer our review question. Because we are looking to establish test accuracy in both primary presentation and referred participants, a study could be appropriate for 1 setting and not for the other, or it could be unclear as to whether the study can appropriately answer either question For each study assessed, please consider whether it is more relevant for A) participants with a primary presentation of a skin lesion or B) referred participants, and respond to the questions in either A) or B) accordingly. If the study gives insufficient details, please respond Unclear to both parts of the question 	<p>A) For studies that will contribute to the analysis of participants with a primary presentation of a skin lesion (i.e. test naive)</p> <p>Yes – if participants included in the study appear to be generally representative of those who might present in a usual practice setting</p> <p>No – if study participants appear to be unrepresentative of usual practice, e.g. in terms of severity of disease, demographic features, presence of differential diagnosis or comorbidity, setting of the study, and previous testing protocols</p> <p>Unclear – if insufficient details are provided to determine the generalisability of study participants</p> <p>B) For studies that will contribute to the analysis of referred participants (i.e. who have already undergone some form of testing)</p> <p>Yes – if study participants appear to be representative of those who might be referred for further investigation. If the study focuses only on those with equivocal lesions, for example, we would suggest that this is not representative of the wider referred population</p> <p>No – if study participants appear to be unrepresentative of usual practice, e.g. if a particularly high proportion of participants have been self-referred or referred for cosmetic reasons. Other factors to consider include severity of disease, demographic features, presence of differential diagnosis or comorbidity, setting of the study, and previous testing protocols</p> <p>Unclear – if insufficient details are provided to determine the generalisability of study participants</p>
<p>2) Did the study avoid including participants with multiple lesions?</p>	<p>Yes – if the difference between the number of included lesions and number of included participants is less than 5%</p> <p>No – if the difference between the number of included lesions and number of included participants is greater than 5%</p> <p>Unclear – if it is not possible to assess</p>
<p>Is there concern that the included participants do not match the review question?</p> <ol style="list-style-type: none"> If the answer to question 1) or 2) 'Yes': If the answer to question 1) or 2) 'No': If the answer to question 1) or 2) 'Unclear': 	<ol style="list-style-type: none"> Concern is low Concern is high Concern is unclear
INDEX TEST (2) RISK OF BIAS (to be completed per test evaluated)	
<p>1) Was the index test or testing strategy result interpreted without knowledge of the results of the reference standard?</p>	<p>Yes – if index test described as interpreted without knowledge of reference standard result or, for prospective studies, if index test is always conducted and interpreted prior to the reference standard</p> <p>No – if index test described as interpreted in knowledge of reference standard result</p> <p>Unclear – if index test blinding is not described</p>

Item	Response (delete as required)
PARTICIPANT SELECTION (1) RISK OF BIAS	
2) Was the diagnostic threshold at which the test was considered positive (i.e. melanoma present) prespecified?	<p>Yes – if threshold was prespecified (i.e. prior to analysing study results)</p> <p>No – if threshold was not prespecified</p> <p>Unclear – if not possible to tell whether or not diagnostic threshold was prespecified</p>
3) For within-person comparisons of index tests or testing strategies (i.e. > 1 index test applied per participant): was each index test result interpreted without knowledge of the results of other index tests or testing strategies?	<p>Yes – if all index tests were described as interpreted without knowledge of the results of the others</p> <p>No – if the index tests were described as interpreted in the knowledge of the results of the others</p> <p>Unclear – if it is not possible to tell whether knowledge of other index tests could have influenced test interpretation</p> <p>N/A – if only 1 index test was evaluated</p>
<p>Could the conduct or interpretation of the index test have introduced bias?</p> <p>For non-comparative and between-person comparison studies</p> <p>1. If answers to questions 1) and 2) 'Yes':</p> <p>2. If answers to either questions 1) or 2) 'No':</p> <p>3. If answers to either questions 1) or 2) 'Unclear':</p> <p>For within-person comparative studies</p> <p>1. If answers to all questions 1), 2), for any index test and 3) 'Yes':</p> <p>2. If answers to any 1 of questions 1) or 2) for any index test or 3) 'No':</p> <p>3. If answers to any 1 of questions 1) or 2) for any index test or 3) 'Unclear':</p>	<p>For non-comparative and between-person comparison studies</p> <p>1. Risk is low</p> <p>2. Risk is high</p> <p>3. Risk is unclear</p> <p>For within-person comparative studies</p> <p>1. Risk is low</p> <p>2. Risk is high</p> <p>3. Risk is unclear</p>
INDEX TEST (2) CONCERN ABOUT APPLICABILITY	
<p>1) Was the diagnostic threshold to determine presence or absence of disease established in a previously published study?</p> <p>E.g. previously evaluated/established</p> <ul style="list-style-type: none"> • algorithm/checklist used • lesion characteristics indicative of melanoma used • objective (usually numerical) threshold used 	<p>Yes – if a previously evaluated/established tool to aid diagnosis of melanoma was used or if the diagnostic threshold used was established in a previously published study</p> <p>No – if an unfamiliar/new tool to aid diagnosis of melanoma was used, if no particular algorithm was used, or if the objective threshold reported was chosen based on results in the current study</p> <p>Unclear – if insufficient information was reported</p>
<p>2) Were thresholds or criteria for diagnosis reported in sufficient detail to allow replication?</p> <p>Study results can only be reproduced if the diagnostic threshold is described in sufficient detail. This item applies equally to studies using pattern recognition and those using checklists or algorithms to aid test interpretation</p>	<p>Yes – If the criteria for diagnosis of melanoma were reported in sufficient detail to allow replication</p> <p>No – if the criteria for diagnosis of melanoma were not reported in sufficient detail to allow replication</p> <p>Unclear – If some but not sufficient information on criteria for diagnosis to allow replication were provided</p>

Item	Response (delete as required)
PARTICIPANT SELECTION (1) RISK OF BIAS	
<p>3) Was the test interpretation carried out by an experienced examiner?</p>	<p>Yes – if the test was interpreted by 1 or more speciality-accredited dermatologists, or by examiners of any clinical background with special interest in dermatology and with any formal training in the use of the test</p> <p>No – if the test was not interpreted by an experienced examiner (see above)</p> <p>Unclear – if the experience of the examiner(s) was not reported in sufficient detail to judge or if examiners were described as 'Expert' with no further detail given</p> <p>N/A – if system-based diagnosis, i.e. no observer interpretation</p>
<p>Is there concern that the index test, its conduct, or interpretation differ from the review question?</p> <p>1. If answers to questions 1), 2), and 3) 'Yes': 2. If answers to questions 1), 2), or 3) 'No': 3. If answers to questions 1), 2), or 3) 'Unclear':</p>	<p>1. Concern is low 2. Concern is high 3. Concern is unclear</p>
REFERENCE STANDARD (3) RISK OF BIAS	
<p>1) Is the reference standard likely to correctly classify the target condition?</p> <p>A) Disease-positive – 1 or more of the following:</p> <ul style="list-style-type: none"> • histological confirmation of melanoma following biopsy or lesion excision • clinical follow-up of benign-appearing lesions for at least 3 months following the application of the index test, leading to a histological diagnosis of melanoma <p>B) Disease-negative – 1 or more of the following:</p> <ul style="list-style-type: none"> • histological confirmation of absence of melanoma following biopsy or lesion excision in at least 80% of disease-negative participants • clinical follow-up of benign-appearing lesions for a minimum of 3 months following the index test in up to 20% of disease-negative participants 	<p>A) Disease-positive</p> <p>Yes – if all participants with a final diagnosis of melanoma underwent 1 of the listed reference standards</p> <p>No – If a final diagnosis of melanoma for any participant was reached without histopathology</p> <p>Unclear – if the method of final diagnosis was not reported for any participant with a final diagnosis of melanoma or if the length of clinical follow-up used was not clear or if a clinical follow-up reference standard was reported in combination with a participant-based analysis and it was not possible to determine whether the detection of a malignant lesion during follow-up is the same lesion that originally tested negative on the index test</p> <p>B) Disease-negative</p> <p>Yes – If at least 80% of benign diagnoses were reached by histology and up to 20% were reached by clinical follow-up for a minimum of 3 months following the index test</p> <p>No – if more than 20% of benign diagnoses were reached by clinical follow-up for a minimum of 3 months following the index test or if clinical follow-up period was less than 3 months</p> <p>Unclear – if the method of final diagnosis was not reported for any participant with benign or non-melanoma diagnosis</p>
<p>2) Were the reference standard results interpreted without knowledge of the results of the index test?</p> <p>Please score this item for all studies even though histopathology interpretation is usually conducted with knowledge of the clinical diagnosis (from visual inspection or dermoscopy or both). We will deal with this by not including the response to this item in the 'Risk of bias' assessment for these tests. For reviews of all other tests, this item will be retained</p>	<p>Yes – if the reference standard diagnosis was reached blinded to the index test result</p> <p>No – if the reference standard diagnosis was reached with knowledge of the index test result</p> <p>Unclear – if blinded reference test interpretation was not clearly reported</p>

Item	Response (delete as required)
PARTICIPANT SELECTION (1) RISK OF BIAS	
<p>Could the reference standard, its conduct, or its interpretation have introduced bias?</p> <p><u>For visual inspection/dermoscopy evaluations</u></p> <p>1. If answer to question 1) 'Yes': 2. If answer to question 1) 'No': 3. If answer to question 1) 'Unclear':</p> <p><u>For all other tests</u></p> <p>1. If answers to questions 1) and 2) 'Yes': 2. If answers to questions 1) or 2) 'No': 3. If answers to questions 1) or 2) 'Unclear':</p>	<p><u>For visual inspection/dermoscopy evaluations</u></p> <p>1. Risk is low 2. Risk is high 3. Risk is unclear</p> <p><u>For all other tests</u></p> <p>1. Risk is low 2. Risk is high 3. Risk is unclear</p>
REFERENCE STANDARD (3) CONCERN ABOUT APPLICABILITY	
<p>1) Are index test results presented separately for each component of the target condition (i.e. separate results presented for those with invasive melanoma, melanoma in situ, lentigo maligna, severe dysplasia, BCC, and cSCC)?</p>	<p>Yes – if index test results for each component of the target condition can be disaggregated</p> <p>No – if index test results for the different components of the target condition cannot be disaggregated</p> <p>Unclear – if not clearly reported</p>
<p>2) Expert opinion (with no histological confirmation) was not used as a reference standard</p> <p>'Expert opinion' means diagnosis based on the standard clinical examination, with no histology or lesion follow-up</p> <p>***do not complete this item for teledermatology studies</p>	<p>Yes – if expert opinion was not used as a reference standard for any participant</p> <p>No – if expert opinion was used as a reference standard for any participant</p> <p>Unclear – if not clearly reported</p>
<p>3) Was histology interpretation carried out by an experienced histopathologist or by a dermatopathologist?</p>	<p>Yes – if histology interpretation was reported to be carried out by an experienced histopathologist or dermatopathologist</p> <p>No – if histology interpretation was reported to be carried out by a less experienced histopathologist</p> <p>Unclear – if the experience/qualifications of the pathologist were not reported</p>
<p>Is there concern that the target condition as defined by the reference standard does not match the review question?</p> <p>1. If answers to all questions 1), 2), and 3) 'Yes': 2. Cristofolini 1997 Pathway – unclear MM+MiS	WPC (algs) NR-CS Italy Secondary	Patients with small and flat common and atypical PSL recruited during a health campaign for the early diagnosis of melanoma; all underwent skin biopsy.	176 / 176	VI (ABCD) In-person	NR	Dermatologist (n=3; High experience) Consensus of 3	Histology MM+MiS 35 BN 141 35/176; 20%	None reported
Ek 2005 Pathway – clear MM+MiS Any	NC P-CS Australia Specialist clinic	Lesions excised for which malignancy could not be excluded	1223 / 2582	VI (no algorithm) In-person	Subjective impression	Plastic surgeon (n=4 or 5; mixed experience; 3 consultants, 1 plastic surgery trainee (usually 1st year, on 6 month rotation) and a clinical assistant) Unclear	Histology MM+MiS 23 BCC 1214; SCC 517; BD 188; SK 63; 577 other benign (including 330 solar keratosis) 23/2582; 1%	Incomplete or incorrectly entered proforma were excluded 79 patients with 96 lesions
Green 1991 Pathway – clear MM+MiS	NC NR-CS Australia Secondary	PSL for excision	81 / 89	VI (no algorithm) In-person	Subjective impression	NR (n=NR; exp NR "in the majority of cases a surgeon or a dermatologist") Single observer	Histology MM+MiS 5 BCC 2; SK 7; BN 54; Other 2 5/70; 7%	19/89 lesions excluded (number participated not reported due to incomplete clinical and histology records.
Langley 2001 Pathway – unclear MM+MiS	NC P-CS US Specialist clinic	Patients with lesions scheduled for excision at the pigmented lesion clinic to either remove atypical nevi or to rule out melanoma or for cosmetic reasons	NR / 38	VI (no algorithm) In-person	NR	NR (presume dermatologist; n=NR; exp NR) Unclear	Histology MM 3; MiS 3 BN 32 6/38; 16%	None reported
Morales Callaghan 2008 Pathway – unclear MM+MiS	WPC P-CS Spain Secondary	Randomly selected melanocytic lesions; melanocytic on both clinical and dermoscopic criteria	166 / 200	1. VI (no algorithm) 2. Dermoscopy (no algorithm) In-person	NR	Dermatologist (n=2; high experience in dermoscopy) Consensus of 2	Histology MM+MiS 6 BN 184; SN 1; Other 9 6/200; 3%	None reported

#164d Visual inspection for the diagnosis of cutaneous melanoma in adults

Study author	Study type Country Setting	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MEL)	Exclusion
Morton 1998a (high exp), Morton 1998b (mod exp) and Morton 1998c (low exp) Pathway – clear MM+MiS	NC R-CS UK Specialist clinic	Patients referred by their GP to the clinic	NR / 1999	VI (no algorithm) In-person	NR	Dermatologist (n=2; high); Dermatology senior registrar (n=1; moderate); Dermatology registrar (n=1; low) Single observer per lesion	Histology MM 104; MiS 24 Benign 1871 High exp: 69/763; 9% Moderate exp: 31/567; 5% Low exp: 28/669; 4%	None reported
Thomas 1998 Pathway – unclear MM+MiS	NC CCS France Secondary	All cases of melanoma and a nonselected consecutive group of 'non-melanoma' PSL	NR / 1140	VI (ABCDE) In-person	>=1 characteristic present >=2 characteristics present >=3 characteristics present >=4 characteristics present all 5 characteristics present	Dermatologist (n=2; High exp - described as 'trained dermatologists') Single observer	Histology MM+MiS 460 BCC 8 BN 638; SN 2; Other 13 460/1140; 40%	None reported
Unlu 2014 Pathway – unclear MM+MiS	WPC (algs) R-CS Turkey Specialist clinic	Melanocytic lesions excised at Department of Dermatology Pigmented Lesion Clinic	115 / 115	1. VI (no algorithm) 2. Dermoscopy (7-point; 3-point; CASH; ABCD) In-person	1. subjective impression 2. score >=3; >=2 characteristics present; score >=8; score >5.44	NR (presume dermatologist; n=1 for VI; n=3 for dermoscopy; Exp NR for VI) Single observer (VI); consensus of 3 (dermoscopy)	Histology MM+MiS 24 BN 91 24/115; 21%	None reported
Zaumseil 1983 Pathway – unclear MM+MiS	NC NR-CS Germany Secondary	Skin lesions undergoing excision	NR / 7063	VI (no algorithm) In-person	Subjective impression	NR (n=NR; exp NR) Single observer	Histology MM+MiS 337 Not melanoma 6726 (dx listed only for FPs) 337/7063; 5%	None reported

5* - Equivocal referred for further assessment (selected for excision)

Study author	Study type Country	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MEL)	Exclusion
Dummer 1993 Pathway – clear MM+MiS	WPC P-CS Germany	Patients with melanocytic skin lesions difficult to diagnose clinically	NR / 771	VI (no algorithm) Dermoscopy (pattern) In-person (I-B for dermoscopy)	NR	NR assume Dermatologist (assumed) (n=2; exp NR) Single observer	Histology MM 19; MiS 4 SK 4; BN 706; Benign NML 32; Other 6 23/771; 3%	53 non-melanocytic lesions not included in the final analysis melanoma present in this group
Soyer 1995 Pathway – clear MM+MiS	WPC NR-CS Austria	PSL difficult to diagnose on clinical grounds alone	NR / 159	VI (no algorithm) Dermoscopy (pattern) In-person	NR	Dermatologist (n=2; exp High; "the examination was performed by a dermatologist expert in dermoscopy") Single observer	Histology MM 50; MiS 15 BCC 3; SK 18; AK 4; BN 61; Other 7 65/159; 41%	None reported
Steiner 1987 Pathway – unclear MM+MiS	P-CS Austria Specialist clinic	Small (< 10 mm) diagnostically equivocal PSL; no absolute agreement on clinical diagnosis among investigating clinicians at a pigmented lesion clinic.	NR / 318	1. VI (no algorithm) 2. Dermoscopy (pattern) In-person	Subjective impression	Dermatologists (n=3; High exp - "experienced dermatologists") Consensus diagnosis of 3 observers	Histology MM 49; MiS 24 BCC 20 BN 143; SK 20; lentigo simplex and nevus lentigo 19; Other 15 73/318; 23%	None reported

NR – not reported; PSL – pigmented skin lesion; PLC – pigmented lesion clinic; MM – malignant melanoma; MiS – melanoma *in situ* (or lentigo maligna); BCC – basal cell carcinoma; cSCC – cutaneous squamous cell carcinoma; LS – lentigo simplex; SK – seborrheic keratosis; SN – Spitz nevi; AK – actinic keratosis; BN – benign naevi; BNM – benign non-melanocytic; BD – Bowen's disease; DF – dermatofibroma; FU – follow-up; R – retrospective; P – prospective; CS – case series; CCS – case control study; WPC – within person comparison (of tests); BPC – between person comparison (of tests); NC – non comparative; exp – experience; GP – general practitioner; VI – visual inspection; RCT – randomised controlled trial; SCC – squamous cell carcinoma; dx – diagnosis; AHM – atypical melanocytic naevi; ELM – epiluminescence microscopy.

10 Summary QUADAS - in-person evaluations

	STUDIES CLEARLY PLACED ON CLINICAL PATHWAY		STUDIES NOT CLEARLY PLACED ON CLINICAL PATHWAY	
Pathway	Risk of Bias	Concerns about applicability	Risk of Bias	Concerns about applicability
2 – Limited prior testing				
Studies	N=3; Grimaldi 2009 ; Menzies 2009 ; Walter 2012		N=0	

#164d Visual inspection for the diagnosis of cutaneous melanoma in adults

Participant selection	Low (3/3)	High (2/3); Unclear (1/3). Inclusion of multiple lesions per participant (Grimaldi 2009 ; Walter 2012); patient numbers not reported (Menzies 2009).		
Index test	Low (1/3); Unclear (2/3). Lack of clear pre-specification of threshold (Grimaldi 2009 ; Menzies 2009)	Low (1/3); High (2/3). Lack of description of diagnostic threshold (Grimaldi 2009 ; Menzies 2009). Non-expert test interpretation (Menzies 2009 ; Walter 2012); not clear in Grimaldi 2009 .		
Reference standard	High (3/3). <80% of disease negative participants had histological or clinical follow up reference standard	High (2/3); Unclear (1/3). Expert diagnosis as reference standard (Menzies 2009 ; Walter 2012); unclear histopathologist expertise (3/3).		
Flow and timing	High (3/3). Mixed reference standards (3/3); participant exclusions (Menzies 2009 ; Walter 2012); all unclear on index to reference interval.			

3 – Limited prior testing (selected for excision)

Studies	N=2; Gachon 2005 ; McGovern 1992		N=1; Collas 1999	
Participant selection	Low (1/2); Unclear (1/2). Unclear exclusion criteria (1/2; Gachon 2005).	High (2/2). Restriction to melanocytic (1/2; Gachon 2005) or primarily excised lesions (2/2); multiple lesions per participant (1/2; McGovern 1992); no. patients not reported (1/2; Gachon 2005)	Unclear (1/1). Participant sampling not described; exclusion criteria not reported	High (1/1). Excised only included
Index test	Unclear (1/2); High (1/2). Lack of clear pre-specification of the threshold (1/2; Gachon 2005) or testing of multiple thresholds (1/2; McGovern 1992)	High (1/2); Unclear (1/2). Lack of threshold detail (1/2; Gachon 2005); unclear description of observer expertise (2/2)	Low (1/1)	Unclear (1/1). Observer expertise not described

Reference standard	Low (2/2)	Low (1/2); Unclear (1/2). Lack of description of histopathology expertise (1/2; Gachon 2005)	Low (1/1).	Unclear (1/1). Histology expertise not described (histologically analysed by different private and hospital pathologists and reviewed by one of the authors).
Flow and timing	High (1/2); Unclear (1/2). Participant exclusions (1/2; McGovern 1992); unclear reference interval (2/2).		Low (1/1)	
4 - Referred for further assessment				
Studies	N=2; Barzegari 2005 ; Stanganelli 2000		N=0	
Participant selection	Low (2/2)	High (2/2). Included excisions for cosmetic reasons (1/2; Barzegari 2005), or multiple lesions per participant (2/2).		
Index test	Low (1/2); Unclear (1/2). Lack of clear pre-specification of the threshold (Barzegari 2005)	High (1/2); Unclear (1/2). Consensus result (1/2; Barzegari 2005); insufficient threshold detail (1/2; Barzegari 2005); observer expertise not clear (2/2).		
Reference standard	Low (1/2); High (1/2). <80% of disease negative participants had histological or clinical follow up reference standard (Stanganelli 2000)	Unclear (2/2). Lack of description of histopathology expertise (2/2)		
Flow and timing	High (1/2); Unclear (1/2). Unclear reference interval (2/2); use of different reference standards (1/2; Stanganelli 2000)			
5 - Referred for further assessment (selected for excision)				
Studies	N=6; Bono 2002 ; Bono 2002b ; Bono 2006 ; Ek 2005 ; Green 1991 ; Morton 1998a ; Morton 1998b ; Morton 1998c *)		N=9; Benelli 1999 ; Carli 2002b ; Cristofolini 1994 ; Cristofolini 1997 ; Langley 2001 ; Morales Callaghan 2008 ; Thomas 1998 ; Unlu 2014 ; Zaumseil 1983	

#164d Visual inspection for the diagnosis of cutaneous melanoma in adults

Participant selection	Low (2/6); High (2/6); Unclear (2/6). Inappropriate (2/6; Bono 2002 ; Ek 2005) or unclear (2/6; Gachon, Morton) exclusions; consecutive recruitment not reported (1/6; Gachon)	High (6/6). Unrepresentative (6/6) participants; all excised. Multiple lesions per participant (2/6; Ek 2005 ; Green 1991) or number of participants not reported (Morton 1998)	High (4/9); Unclear (5/9). Inappropriate exclusions (4/9) due to restriction to melanocytic only (Morales Callaghan 2008 ; Unlu 2014), disagreement on histology (Zaumseil 1983). Use of case control type design (1/9; Thomas 1998). Unclear participant sampling (6/9; Benelli 1999 ; Carli 2002b , Cristofolini 1994 , Cristofolini 1997 , Langley 2001 ; Zaumseil 1983).	High (9/9). Inclusion of only excised lesions (9/9). Multiple lesions per participant (2/9; Langley 2001 , Morales Callaghan 2008); number of participants not reported (6/9; Benelli 1999 , Carli 2002b , Cristofolini 1994 , Cristofolini 1997 , Thomas 1998 , Zaumseil 1983)
Index test	Low (3/6); Unclear (3/6). Pre-specification of threshold not reported (Ek 2005 ; Green 1991 ; Morton 1998)	High (6/6). All clinically applicable application of test. No threshold details (6/6). Observer experience unclear (3/6; Bono 2006 ; Ek 2005 ; Green 1991).	Low (2/9); High (2/9), Unclear (5/9). Threshold not prespecified (2/9; Benelli 1999 , Thomas 1998) or not clear whether prespecified (Carli 2002b , Cristofolini 1997 , Langley 2001 , Morales Callaghan 2008 , Unlu 2014).	Low (1/9); High (7/9), Unclear (1/9). Test application not clinically applicable (4/9; Benelli 1999 ; Carli 2002b ; Cristofolini 1997 ; Morales Callaghan 2008) or not clear (Cristofolini 1994 ; Langley 2001). No threshold detail (5/9; Carli 2002b ; Langley 2001 ; Morales Callaghan 2008 ; Unlu 2014 ; Zaumseil 1983)
Reference standard	Low (5/6); High (1/6). Inadequate reference standard (1/6; Green 1991)	Low (1/6); High (1/6); Unclear (4/6). Expert diagnosis used (1/6; Green 1991). Lack of description of histopathology expertise (5/6; all except Morton 1998)	Low (9/9)	Low (2/9); High (1/9); Unclear (6/9). Use of expert diagnosis (1/9; Langley 2001). Histopathology expertise not reported (7/9; Benelli 1999 ; Carli 2002b ; Cristofolini 1994 ; Cristofolini 1997 ; Langley 2001 ; Morales Callaghan 2008 ; Zaumseil 1983)
Flow and timing	High (2/6); Unclear (4/6). Index to reference interval not reported (5/6; Bono 2002 ; Bono 2006 ; Green 1991 ; Morton 1998). Participant exclusions due to incomplete data (2/6; Green 1991 ; Ek 2005)		Low (3/9); Unclear (6/9). Interval to reference standard not reported (6/9; Benelli 1999 ; Cristofolini 1994 ; Langley 2001 ; Thomas 1998 ; Unlu 2014 ; Zaumseil 1983)	

5* - Equivocal referred for further assessment (selected for excision)

Studies	N=2; Dummer 1993 ; Soyer 1995		N=1; Steiner 1987	
Participant selection	Unclear (2/2). Unclear sampling methods (2/2); Unclear exclusions (1/2; Soyer 1995)	High (1/2); Unclear (1/2). Participants not representative (1/2; Dummer 1993) or unclear (1/2; Soyer 1995). Number of participants not reported (2/2)	Unclear (1/1). Participant sampling not described; exclusion criteria not reported	High (1/1). Restricted to small <10mm pigmented skin lesions; all excised
Index test	Unclear (2/2). Pre-specification of threshold not reported (2/2)	High (2/2). No threshold details (2/2). Observer experience unclear (1/2; Dummer 1993)	Unclear (1/1). Pre-specification of threshold not reported.	High (1/1). Consensus decision reported and no threshold detail.

Reference standard	Low (2/2)	Unclear (2/2). Lack of description of histopathology expertise (2/2)	Low (1/1).	Unclear (1/1). Histology expertise not described
Flow and timing	High (1/2), Unclear (1/2). Participant exclusions (1/2; Dummer 1993). Index to reference interval not reported (2/2)		Low (1/1).	

11 Summary study details – image-based evaluations

Study author	Study type Country Setting	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MM+MiS)	Exclusions
3 – Limited prior testing (with selection on reference standard)								
Bourne 2012 Pathway - clear	WPC-tests R-CS Australia Primary	All skin lesions excised to exclude skin cancer (and 3 examples common lesions assessed as clearly benign and not biopsied)	46 / 50	VI (no algorithm) Dermoscopy (3-point; Menzies; BLINCK (excluded)) Image-based (blinded)	NR	GP (n=3) Clinical nurse (n=1) Mixed experience “varying levels of dermatoscopic experience” Average	Histology / Clinical FU / Expert dx MM 1; MiS 8 BCC 6; SK 5; BN 11; Other 19 9/45; 20%	5 non-pigmented specimens (not further identified) in the set of 50 were excluded from dermatoscopic evaluations
Rosendahl 2011 Pathway – unclear	NC R-CS Australia Primary	PSL submitted for histology from the primary care skin cancer practice of one author	389 / 463	1. VI (no algorithm) 2. Dermoscopy (pattern)	1. subjective impression 2. both characteristics present	Dermatologist (n=1) Image-based; High experience (confirmed by author); Single observer	Histology MM 9; MiS 20 BCC 72; SCC 5 BN 217; BD 18; AK 14*; BNM 140 * considered malignant by study authors 29/463; 6%	3 poor quality images excluded
4 - Referred for further assessment								
Stanganelli 2005 Pathway - clear MM+MiS	WPC R-CS Italy Specialist clinic	Melanocytic lesions referred to Skin Cancer Unit for clinical and dermoscopic evaluation.	NR / 477	VI (no algorithm) Dermoscopy (no algorithm) Image-based (Average)	NR	Dermatologist (n=3); GP (n=3) Dermatologists - High experience (“2 years dermoscopy experience”); experience NR for GPs, assumed Low	Histology / Registry FU MM+MiS 31 BN 103 31/134; 23%	None reported

Study author	Study type Country	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MM+MiS)	Exclusions
5 - Referred for further assessment (with selection on reference standard)								
Benelli 2001 Pathway – unclear	WPC R-CS Italy Training images	Slides of PSL selected for evaluation during a training course on dermoscopy. Lesions not located on head, palms or soles	NR / 49	1. VI (ABCDE) 2. Dermoscopy (7FFM)	1. >=3 & >=2 2. >=2	Expert author (n=1); Dermatologists (n=65) Image-based; Single author - High experience; Average result for dermatologist group; experience NR	Histology MM 10, MiS 2 BCC 2 BN 25, SN 5, SK 3, Other 2 (1 missing) 12/50; 24%	None reported
Carli 2002b Pathway – unclear	WPC R-CS Italy Secondary	Clinically suspicious or equivocal PSL undergoing excision for diagnostic purposes; all <= 14mm diameter	NR / 57	1. VI (NR) 2. Dermoscopy (NR)	NR	Dermatologists (n=2) Image-based; high experience ('with experience in the field of PSL'); consensus of 2	Histology MM 6, MiS 5 BCC 10 BN 31, SK 1; Other 4 11/57; 19%	4 'not evaluables' excluded (1MM, 3 benign)
Dolianitis 2005 Pathway – unclear	WPC CCS Multi-centre Training images	Melanocytic skin lesions selected from a collection of dermoscopic images belonging to one author.	NR / 40	1. VI (no algorithm) 2. Dermoscopy (Pattern analysis; Menzies Criteria; 7 point; ABCD)	1. subjective impression 2. subjective impression; NR; NR; >4.75	Dermatologists(n=16); dermatology trainees (n=16); GPs (n=35) Image-based; mixed experience ("range of experience levels with assessment of skin lesions"); average result	Histology (n=39); Expert diagnosis (n=1) MM 18, MiS 2 BN 12; SN 3; Other 4 20/20; 50%	None reported; poor quality images exclusion criterion
Pizzichetta 2004 Pathway – unclear	WPC R-CS US/Italy Secondary	Clinical and/or dermoscopic hypomelanotic (extent of pigmentation <=30%) and amelanotic skin lesions	151 / 151	1. VI (no algorithm) 2. Dermoscopy (pattern)	subjective impression	NR (presume dermatologist; n=1) Image-based; experience NR; single observer	Histology AHM 34, MiS 5 BCC 25, SCC 5 BN 47, SN 5, SK 8, Other 18 39/108; 36% (analysed)	23 lesions excluded due to image quality; further 43 lesions were not available for evaluation by clinical images ("mainly benign melanocytic lesions").

Study author	Study type Country Setting	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MM+MiS)	Exclusions
Stanganelli 1998 Pathway – unclear	WPC R-CS Italy Training images	PSL images selected from computerised files of the skin cancer clinic.	NR / 30	1. VI (no algorithm) 2. Dermoscopy (no algorithm)	NR	Dermatologists (n=20) Image-based; experience NR (“experience in ELM but (with) no formal training”); average	Histology MM+MiS 10 BCC 4 BN 10, SK 3, Other 3 10/30; 33%	None reported
Winkelmann 2016 Pathway – unclear	WPC CCS Unclear Training images	Selected images previously analysed by MSDSLA	NR / 12	1. VI (no algorithm) 2. Dermoscopy (no algorithm)	NR	Dermatologists (n=70) Image-based; experience NR; average	Histology MM 3; MiS 2 BN 7 5/12; 42%	None reported
5* - Equivocal referred for further assessment (with selection on reference standard)								
Carli 2003b Pathway – unclear	WPC R-CS Italy Secondary	Clinically difficult to diagnose or equivocal melanocytic lesions randomly selected from image database; all melanomas <1mm thickness.	NR / 200	1. VI (no algorithm) 2. Dermoscopy (own choice)	subjective impression	Dermatology registrar (n=2); dermatologists (senior experts n=2; practicing dermatologists n=4) Classed as High experience (both dermatologists and registrars “formally trained in dermoscopy”); Average result	Histology MM 40; MiS 24 BN 136 64/200; 32%	None reported
de Giorgi 2012 Pathway – unclear	WPC R-CS Italy Secondary	Pigmented melanocytic skin lesions <= 6mm diameter excised at dermatology department	NR / 103	VI (ABCD)	1. >=2 characteristics present 2. >=3 characteristics present	Dermatologists (n=3) High experience (“more than 5 years of practice in dermoscopy”); consensus of 3	Histology MM 16; MiS 18 BN 69 34/103; 33%	None reported

NR – not reported; PSL – pigmented skin lesion; PLC – pigmented lesion clinic; MM – malignant melanoma; MiS – melanoma *in situ* (or lentigo maligna); BCC – basal cell carcinoma; cSCC – cutaneous squamous cell carcinoma; LS – lentigo simplex; SK – seborrhoeic keratosis; SN – Spitz nevi; AK – actinic keratosis; BN – benign naevi; BD – Bowen’s disease; DF – dermatofibroma; FU – follow-up; R – retrospective; P – prospective; CS – case series; CCS – case control study; WPC – within person comparison (of tests); BPC – between person comparison (of tests); NC – non comparative; GP – general practitioner; VI – visual inspection; RCT – randomised controlled trial; SCC – squamous cell carcinoma; dx – diagnosis; ELM – epiluminescence microscopy; BLINCK – Benign Lonely irregular Nervous Change Known Clues; BNM – benign non-melanocytic; AHM – amelanotic/hypomelanotic melanoma; MSDSLA – multispectral digital skin lesion analysis device.

12 Summary QUADAS - image-based evaluations

STUDIES CLEARLY PLACED ON CLINICAL PATHWAY	STUDIES NOT CLEARLY PLACED ON CLINICAL PATHWAY
---	---

Pathway	Risk of Bias	Concerns about applicability	Risk of Bias	Concerns about applicability
3 – Limited prior testing (with selection on reference standard)				
Studies	N=1; Bourne 2012		N=1; Rosendahl 2011	
Participant selection	Unclear (1/1). Unclear exclusion criteria (Bourne 2012).	High (1/1). Restriction to primarily excised lesions (1/1)	Low (1/1).	High (1/1). Includes excised lesions only; multiple lesions per participant.
Index test	Unclear (1/1) Lack of clear pre-specification of the threshold (Bourne 2012).	High (1/1). Blinded image interpretation and average observer result presented (Bourne 2012); lack of threshold detail (Bourne 2012); unclear description of observer expertise	Unclear (1/1). No clear pre-specification of threshold.	High (1/1). Image-based study; no threshold detail.
Reference standard	Low (1/1)	High (1/1) Use of expert diagnosis as reference (Bourne 2012); lack of description of histopathology expertise (Bourne 2012)	Low (1/1).	Unclear (1/1). Histopathology experience not reported.
Flow and timing	High (1/1) Use of different reference standards (Bourne 2012); participant exclusions (Bourne 2012).		High (1/1). Exclusions on image quality Unclear interval between index and reference.	
4 - Referred for further assessment				
Studies	N=1; Stanganelli 2005		N=0	
Participant selection	Unclear (1/1). Unclear participant sampling across all items (Stanganelli 2005)	High (1/1). Sample restricted to melanocytic lesions (Stanganelli 2005). Patient numbers not reported,		

Index test	Unclear (1/1). Lack of clear pre-specification of the threshold (Stanganelli 2005)	High (1/1). Average result presented (Stanganelli 2005); insufficient threshold detail (Stanganelli 2005).		
Reference standard	Low (1/1)	Unclear (1/1). Unclear use of expert diagnosis as reference standard (Stanganelli 2005). Unclear histopathology expertise		
Flow and timing	High (1/1) Use of different reference standards (Stanganelli 2005); unclear reference interval.			
5 - Referred for further assessment (with selection on reference standard)				
Studies	N=0	N=6; Benelli 2001 ; Carli 2002b ; Dolianitis 2005 ; Pizzichetta 2004 ; Stanganelli 1998 ; Winkelmann 2016		
Participant selection		High (3/6), Unclear (3/6). Case control type design used (3/3; Dolianitis 2005 ; Stanganelli 1998 , Winkelmann 2016) or unclear design (Benelli 2001 ; Pizzichetta 2004). Unclear participant sampling (5/6; Benelli 2001 , Carli 2002b , Pizzichetta 2004 , Stanganelli 1998 , Winkelmann 2016), design unclear (1/6), exclusion criteria not clearly reported (5/6; Benelli 2001 , Carli 2002b , Dolianitis 2005 , Stanganelli 1998 , Winkelmann 2016).	High (6/6). Excised only included (6/6), amelanotic/ hypomelanotic lesions only (1/6; Pizzichetta 2004). Number participants not reported (5/6; Benelli 2001 , Carli 2002b , Dolianitis 2005 , Stanganelli 1998 , Winkelmann 2016)	

Index test			Low (1/6); Unclear (5/6). No clear pre-specification of threshold (5/6; Carli 2002b , Dolianitis 2005 , Pizzichetta 2004 , Stanganelli 1998 , Winkelmann 2016).	High (6/6). Image-based evaluations (6/6), blinded to all other information (5/6; Benelli 2001 , Carli 2002b , Dolianitis 2005 , Stanganelli 1998 , Winkelmann 2016), with consensus (1/6; Carli 2002b) or average result (4/6; Benelli 2001 , Dolianitis 2005 , Stanganelli 1998 , Winkelmann 2016) reported. Threshold not clearly specified (5/6; Carli 2002b , Dolianitis 2005 , Pizzichetta 2004 , Stanganelli 1998 , Winkelmann 2016). Observer expertise not reported (4/6; Dolianitis 2005 ; Pizzichetta 2004 ; Stanganelli 1998 ; Winkelmann 2016)
Reference standard			Low (6/6)	High (1/6); Unclear (5/6). Use of expert observer diagnosis (1/6; Dolianitis 2005); expertise of histopathologist not described (6/6).
Flow and timing			Low (1/6); High (2/6); Unclear (3/6). Lesions excluded from analysis (reason not reported) (2/6; Dolianitis 2005 ; Pizzichetta 2004); different reference standards used (1/6; Dolianitis 2005). Index to reference interval not reported (5/6; Benelli 2001 , Dolianitis 2005 , Pizzichetta 2004 , Stanganelli 1998 , Winkelmann 2016).	

5* - Equivocal referred for further assessment (with selection on reference standard)

Studies	N=0	N=2; Carli 2003b ; de Giorgi 2012		
Participant selection			High (2/2). Exclusion of difficult to diagnose, including peculiar lesions (1/2; Carli 2003b), histology disagreement (1/2; de Giorgi 2012).	High (2/2). Restriction to melanocytic only (2/2), excised only (2/2). Patient numbers not reported (2/2)
Index test			High (1/2), Unclear (1/2). Multiple thresholds tested (1/2; de Giorgi 2012); no clear threshold specification (1/2; Carli 2003b).	High (2/2). Image-based evaluations (2/2), blinded to all other information (1/2; Carli 2003b), with consensus (1/2; de Giorgi 2012) or average result (1/2; Carli 2003b) reported. Threshold not described (1/2; Carli 2003b)
Reference standard			Low (2/2)	Low (2/2)
Flow and timing			Unclear (2/2). Index to reference interval not reported (2/2).	

13 Summary study details – detection of invasive melanoma alone

Study author	Study type	Inclusion criteria	No. patients / lesions	Index tests (algorithm)	Threshold	Observer qual. (n)	Reference standard	Exclusions

	Setting						Prevalence (MM+MiS)	
In-person								

#164d Visual inspection for the diagnosis of cutaneous melanoma in adults

Study author	Study type Country Setting	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MM+MiS)	Exclusions
Bono 1996	WPC-tests Unclear Italy Specialist clinic	Pigmented skin lesions at the Istituto Nazionale Tumori of Milan	45 / 54	VI (no algorithm) Single observer	Subjective impression	Plastic surgeon	Histology plus other (31% of benign had expert dx) MM: 18 BN: 25 18/43; 42%	Only 43 lesions had complete clinical and histological information. 11 lesions not surgically removed had only clinical diagnosis (benign) and were not included in the final accuracy analysis
Green 1994	NC NR-CS Australia Secondary	Pigmented lesions for excision	129 / 164	VI (no algorithm) Single observer	Subjective impression; clinical dx recorded	NR	Histology MM 18; MiS 3 BN 128; misc pigmented lesions including SK, BCC, lentiginos 15 18/164; 11%	
Kopf 1975	NC R-CS US Specialist clinic	All lesions subject to biopsy at the Oncology Section of the Skin and Cancer Unit.	NR / 5538	VI (no algorithm) Single observer	No details; 'clinical diagnosis'	Oncologist	Histology MM 99 Other dx listed only for false positives 99/5538; 2%	
Krahn 1998	WPC-tests P-CS Germany Secondary	Excised pigmented skin lesions	80 / 80	VI (no algorithm) Single observer	no details	Dermatologist (assumed)	Histology MM 39 BN 40; SN 1 39/80; 49%	
McGovern 1992	WPC-algs P-CS US Community Pathway - clear Pathway - clear	PSL (>10mm) excised to rule out dysplasia, lentigo maligna or malignant melanoma	179 / 237	VI (7-point; (A)BCD) In-person; Single	7-point: >=2, >=3, >=4 characteristics present (A)BCD: >=1, >=2, >=3 characteristics present	NR (presume dermatologist) experience. NR	Histology MM 6; MiS 6 BCC 4; SK 32; BN 138; AK 6; Other 45 6/211; 3%	32 lesions unaccounted for; 13 excluded due to lesion size of 8mm or less. 192 evaluated for ABCD and 3-point; 205 evaluated for 7 point

Study author	Study type	Inclusion criteria	No. patients / lesions	Index tests (algorithm)	Threshold	Observer qual. (n)	Reference standard	Exclusions
Outcomes reported	Country			Diagnostic approach		Experience	Final diagnoses	
	Setting						Prevalence (MM+MiS)	
Viglizzo 2004	WPC-tests NR-CS Italy Specialist clinic	Pigmented skin lesions examined at the Dermoscopy Service and undergoing excisions; high and medium risk on dermoscopy were selected for excision and 2x2 can be estimated only for melanocytic subgroup.	NR / 79	VI (no algorithm) Single observer	No details	Dermatologist (assumed)	Histology Melanoma (invasive): 11; Melanoma (in situ): 1 Melanocytic lesion: 57 11/67 16%	
Walter 2012	BPC RCT UK Primary Pathway - clear MM MM+MiS Any	Any suspicious PSL that could not immediately be diagnosed as benign	654/792 (control arm only)	VI (7-point) Siascope (iv arm) In-person (Single)	NR	GP (n=28) Nurse practitioner. (n=2) Low (excluded if specialist dermatology training)	Histology/Clinical FU(3-6 months)/Expert dx Control group only: MM 16; MiS 2 BCC 4; SK 20; DF 2; lentigo 5; 'benign' 686; unknown 10 16/773 2%	19 (5 due to violation of recruitment criteria or discontinued protocol; 1 died; 4 did not attend for dermatology assessment; 2 missing histology; 7 not clearly accounted for)
Image-based								
Lorentzen 1999	WPC-tests P-CS Denmark Secondary	Patients with lesions suspicious for CMM referred to outpatients clinic	232 / 232	VI (no algorithm) [Dermoscopy] Single observer	Subjective impression; clinical diagnosis	Dermatologist	Histology MM 49 'malignant melanoma' BCC 16, SK 12; BN: 137 Other: 18 (including SN, BD, and others) 49/232; 21%	Poor quality index test image 10 cases excluded
Rao 1997	WPC-algs (tests) R-CS US Private	Patients with atypical melanocytic lesions or suspected early malignant melanoma	63 / 72	VI (ABCD) [Dermoscopy] Single observer	Diagnosis of melanoma	Dermatology registrar	Histology MM 21 Atypical melanocytic nevus 51 21/72; 29%	None

Study author	Study type	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MM+MiS)	Exclusions
Scope 2008	NC R-CS New Zealand Industry image database	Images of pigmented skin lesions selected from a database of standardised patient images provided by a New Zealand-based teledermatology company (MoleMap); images were selected on the basis that (1) at least 8 clinically atypical nevi were apparent on the back; (2) most of the lesions on the back and all of the atypical nevi had close-up clinical digital images; (3) 1-year follow-up images (close-up clinical and dermoscopic images) were available to show that lesions considered to be benign were in fact biologically indolent by revealing no change; and (4) the image quality of both the overview and the close-up images were acceptable	12 / 145	VI (Ugly duckling) Single observer	Lesion id as 'completely different' or somewhat different from the other moles; (Bx) decision.	Dermatologist	Histology or FU MM 5 'malignant melanoma' BN: 140 5/145; 3%	Unacceptable image quality
Trojanova 2003	BPC/WPC-tests R-CCS NR Training images (source NR)	Images of pigmented skin lesions selected for a dermoscopy training study	NR / 50	VI (no algorithm) [Dermoscopy] Single observer	Subjective impression; dx of melanoma	Dermatologist	Histology MM: 25 'Benign': 25 25/50; 50%	NR

#164d Visual inspection for the diagnosis of cutaneous melanoma in adults

Study author	Study type Country	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MM+MiS)	Exclusions
Westerhoff 2000	WPC-tests R-CCS Australia Training images (Specialist unit)	Clinically atypical pigmented skin lesions; 50 invasive melanomas and 50 nonmelanomas randomly selected from the Sydney Melanoma Unit pigmented skin lesions (PSL) image database.	NR / 100	VI (no algorithm) [Dermoscopy] Single observer	Subjective impression; dx of melanoma	GP	Histology or FU MM 50 'Benign':50 50/100; 50%	None

NR – not reported; PSL – pigmented skin lesion; PLC – pigmented lesion clinic; MM – malignant melanoma; MiS – melanoma *in situ* (or lentigo maligna); BCC – basal cell carcinoma; SK – seborrhoeic keratosis; SN – Spitz nevi; AK – actinic keratosis; BN – benign naevi; BD – Bowen’s disease; DF – dermatofibroma; FU – follow-up; R –retrospective; P – prospective; CS – case series; CCS – case control study; WPC – within person comparison (of tests); BPC – between person comparison (of tests); NC – non comparative; VI - visual inspection; RCT - randomised controlled trial; FU - follow-up; Bx - biopsy; CMM - cutaneous malignant melanoma.

14 Summary study details – detection of any skin lesion requiring excision

Study author	Study type Country	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MM+MiS)	Exclusions
In person								
Argenziano 2006 Any	RCT Italy, Spain Primary	Patients asking for screening or exhibiting one or more skin tumours as seen during routine physical examination (patient-finding screening). Participating PCPs randomised to either visual inspection alone or visual inspection plus dermoscopy; only excised lesions can be included for each arm.	NR / 85	VI (ABCD) Dermoscopy (3-point checklist) In person (single observer)	Subjective impression ; dx of malignancy	GPs (n=37) All trained in ABCD rule	Histology MM+MiS 6 BCC 37; SCC 10 Benign 32 53/85; 62%	Only those patients who were considered to have lesions suggestive of skin cancer had histology and could be included; rest had expert diagnosis (making full dataset ineligible for this review)

Study author	Study type Country	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MM+MiS)	Exclusions
Chang 2013 Any	NC R-CS Taiwan Secondary	Potentially malignant biopsied or excised skin lesions (nontumour specimens excluded)	676 / 769	VI (no algorithm) In person (single observer)	Subjective impression; definitely malignant	Dermatologists; n= 25 Board-certified	Histology MM 4; MiS 4 BCC: 110; cSCC: 20 'Benign' diagnoses: 595 152/769; 20%	Poor quality index test image mis-registered or poor quality images (unfocused or containing a motion artifact)
Ek 2005 Pathway – clear MM+MiS Any	NC P-CS Australia Specialist clinic	Lesions excised for which malignancy could not be excluded	1223 / 2582	VI (no algorithm) In person	Subjective impression	Plastic surgeon (n=4 or 5; mixed experience; 3 consultants, 1 plastic surgery trainee (usually 1st year, on 6 month rotation) and a clinical assistant) Unclear	Histology MM+MiS 23 BCC 1214; SCC 517; BD 188; SK 63; 577 other benign (including 330 solar keratosis) 1754/2582; 68%	Incomplete or incorrectly entered proformas were excluded – 79 patients with 96 lesions
McGovern 1992 Pathway – clear	WPC-algs P-CS US Community	PSL (>10mm) excised to rule out dysplasia, lentigo maligna or malignant melanoma	179 / 237	VI (7-point; (A)BCD) In person; Single	7-point: >=2, >=3, >=4 characteristics present (A)BCD: >=1, >=2, >=3 characteristics present	NR (presume dermatologist) experience. NR	Histology MM 6; MiS 6 BCC 4; SK 32; BN 138; AK 6; Other 45 15/192; 8%	32 lesions unaccounted for; 13 excluded due to lesion size of 8mm or less. 192 evaluated for ABCD and 3-point; 205 evaluated for 7 point
Stanganelli 2000 Pathway – clear MM+MiS Any	WPC R-CS Italy Specialist clinic	PSL referred by dermatologists and general practitioners either for pre-surgical assessment or consultation	NR / 3372	VI (ABCD) Dermoscopy (no algorithm) In person (Single)	NR Subjective impression	NR (assumed dermatologist - described as one of the co-authors; n=1)	Histology / Registry FU MM+MiS 55 BCC 43; Benign 3274 98/3372; 3%	None reported

Study author	Study type Country	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MM+MiS)	Exclusions
Steiner 1987 Pathway – unclear MM+MiS	P-CS Austria Specialist clinic	Small (< 10 mm) diagnostically equivocal PSL; no absolute agreement on clinical diagnosis among investigating clinicians at a pigmented lesion clinic.	NR / 318	1. VI (no algorithm) 2. Dermoscopy (pattern) In person	Subjective impression	Dermatologists (n=3; High experience - "experienced dermatologists") Consensus diagnosis of 3 observers	Histology MM 49; MiS 24 BCC 20 BN 143; SK 20; lentigo simplex and nevoid lentigo 19; Other 15 93/318; 29%	None reported
Walter 2012 Pathway - clear MM MM+MiS Any	BPC RCT UK Primary	Any suspicious PSL that could not immediately be diagnosed as benign	654/792 (control arm only)	VI (7-point) Siascope (iv arm) In person (Single)	NR	GP (n=28) Nurse practitioner (n=2) Low (excluded if specialist dermatology training)	Histology/Clinical FU(3-6 months)/Expert dx Control group only: MM 16; MiS 2 BCC 4; SK 20; DF 2; lentigo 5; 'benign' 686; unknown 10 22/773; 3%	19 (5 due to violation of recruitment criteria or discontinued protocol; 1 died; 4 did not attend for dermatology assessment; 2 missing histology; 7 not clearly accounted for)
Image-based								
Carli 2002b Pathway – unclear	WPC R-CS Italy Secondary	Clinically suspicious or equivocal PSL undergoing excision for diagnostic purposes; all <= 14mm diameter	NR / 57	1. VI (NR) 2. Dermoscopy (NR)	NR	Dermatologists (n=2) Image-based; high experience ('with experience in the field of PSL'); consensus of 2	Histology MM 6, MiS 5 BCC 10 BN 31, SK 1; Other 4 20/54; 37%	4 'not evaluables' excluded (1 MM, 3 benign)
Rosendahl 2011 Pathway – unclear	NC R-CS Australia Primary	PSL submitted for histology from the primary care skin cancer practice of one author	389 / 463	1. VI (no algorithm) 2. Dermoscopy (pattern)	1. subjective impression 2. both characteristics present	Dermatologist (n=1) Image-based; High experience (confirmed by author); Single observer	Histology MM 9; MiS 20 BCC 72; SCC 5 BN 217; BD 18; AK 14*; BNM 140 * considered malignant by study authors 104/463; 22%	3 poor quality images excluded

Study author	Study type Country	Inclusion criteria	No. patients / lesions	Index tests (algorithm) Diagnostic approach	Threshold	Observer qual. (n) Experience	Reference standard Final diagnoses Prevalence (MM+MiS)	Exclusions
Stanganelli 1998 Pathway – unclear	WPC R-CS Italy Training images	PSL images selected from computerised files of the skin cancer clinic.	NR / 30	1. VI (no algorithm) 2. Dermoscopy (no algorithm)	NR	Dermatologists (n=20) Image-based; experience NR (“experience in ELM but (with) no formal training”); average	Histology MM+MiS 10 BCC 4 BN 10, SK 3, Other 3 14/30; 47%	None reported

NR – not reported; PSL – pigmented skin lesion; PLC – pigmented lesion clinic; MM – malignant melanoma; MiS – melanoma *in situ* (or lentigo maligna); BCC – basal cell carcinoma; cSCC – cutaneous squamous cell carcinoma; SK – seborrheic keratosis; SN – Spitz nevi; AK – actinic keratosis; BN – benign naevi; BD – Bowen’s disease; DF – dermatofibroma; FU – follow-up; R – retrospective; P – prospective; CS – case series; CCS – case control study; WPC – within person comparison (of tests); BPC – between person comparison (of tests); NC – non comparative; GP - general practitioner; VI - visual inspection; RCT - randomised controlled trial; SCC - squamous cell carcinoma; dx - diagnosis; ELM – epiluminescence microscopy; PCP - primary care practitioner; WPC-als - within person comparison of algorithms.
