**Competing interests**

This trial is funded by the UK Stroke Association which includes salaries for EC.

The sponsor (University of Liverpool Research Support Office) and funder (the Stroke Organisation) had no role in the study design, collection, management, analysis, interpretation of data, writing of the report; and the decision to submit the protocol for publication.

**Author contributions**

FR, GB, RB, AD, MGF, SJ, CM, CN, AP, JR and CS conceived of the study, participated in the design and coordination, and helped to draft the manuscript. EB, CD, CH and TS participated in the coordination and helped to draft the manuscript. MGF supervised the statistical analysis. EJC wrote the statistical analysis plan, performed the statistical analysis, participated in the coordination and data monitoring and helped to draft the manuscript. EC participated in the coordination, performed data entry and helped to draft the manuscript. All authors read and approved the final manuscript.

**Abbreviations**

VISION: vision impairment in stroke: intervention or not

UK: United Kingdom

NHS: National health Service

RNIB: Royal National Institute for the Blind

**Abstract**

Objective: Pilot trial comparing prism therapy and visual search training, for homonymous hemianopia, to standard care (information only).

Methods: Prospective, multicentre, parallel, single-blind, three-arm RCT across fifteen UK acute stroke units.

Participants: Stroke survivors with homonymous hemianopia.

Interventions: Arm a (Fresnel prisms) for minimum 2 hours, 5 days/week over 6-weeks. Arm b (visual search training) for minimum 30 minutes, 5 days/week over 6-weeks. Arm c (standard care-information only).

Inclusion criteria: Adult stroke survivors (>18 years), stable hemianopia, visual acuity better than 0.5logMAR, refractive error within  $\pm 5$ Dioptres, ability to read/understand English, and provide consent.

Outcomes: Primary outcomes were change in visual field area from baseline to 26 weeks and calculation of sample size for a definitive trial. Secondary measures included Rivermead Mobility Index, Visual Function Questionnaire 25/10, Nottingham Extended Activities of Daily Living, Euro Qual, Short Form-12 questionnaires and Radner reading ability. Measures were post-randomisation at baseline and 6, 12, 26 weeks.

Randomisation: Randomisation block lists stratified by site and partial/complete hemianopia.

Blinding: Allocations disclosed to patients. Primary outcome assessor blind to treatment allocation.

Results: 87 patients were recruited: 27 - Fresnel prisms, 30 – visual search training and 30 - standard care. 69% male; mean age 69 years (SD 12). At 26 weeks, full results for 24, 24 and 22 patients respectively were compared to baseline. Sample

4  
5  
6  
7 size calculation for a definitive trial determined as 269 participants per arm for a 200  
8 degree<sup>2</sup> visual field area change at 90% power. Non-significant relative change in  
9 area of visual field was 5%, 8% and 3.5% respectively for the three groups. Visual  
10 Function Questionnaire responses improved significantly from baseline to 26 weeks  
11 with visual search training (60 (SD19) to 68.4 (SD20)) compared to Fresnel prisms  
12 (68.5 (SD16.4) to 68.2 (18.4): 7% difference) and standard care (63.7 (SD19.4) to  
13 59.8 (SD22.7): 10% difference), p=0.05. Related adverse events were common with  
14 Fresnel prisms (69.2%; typically headaches).

15  
16  
17  
18  
19  
20  
21  
22 Conclusions: No significant change occurred for area of visual field area across arms  
23 over follow-up. Visual search training had significant improvement in vision-related  
24 quality of life. Prism therapy produced adverse events in 69%. Visual search training  
25 results warrant further investigation.

## Introduction

Homonymous hemianopia results in loss of one half of the visual field in both eyes [1,2]. The reported prevalence of visual field loss following stroke has been as high as 63% [3] in hospital populations although estimates vary widely as the proportion testing positive is highly dependent on time post stroke. Visual field defects can seriously impact functional ability and quality of life following stroke [4,5]. Patients with visual field defects have an increased risk of falling [6], impaired ability to read, poor mood and institutionalization [6-9]. Visual field loss may impact on a patient's ability to participate in rehabilitation, and may ultimately result in poor long term recovery [8]. Visual field loss can result in accidents or injuries which have subsequent cost implications to the NHS and the patient [10].

Two key interventions commonly used in the clinical setting to improve vision in hemianopia are visual search compensatory training and provision of prisms [11]. A Cochrane systematic review [11] evaluated the interventions for homonymous hemianopia and found evidence in favour of visual search training. Subsequently, Aimola and colleagues [12] conducted a trial of visual search training for homonymous hemianopia and reported evidence of improved quality of life in the intervention group. The Cochrane review did not find sufficient evidence for prisms as an intervention for hemianopia.

The aim of this pilot trial was to compare visual rehabilitation interventions with NHS standard care, in patients with hemianopia following stroke. We wished to explore whether visual rehabilitation was more effective than standard care (advice only) at improving functional outcome in patients with hemianopia following stroke, and whether prism therapy or visual search therapy was more effective at improving functional outcome in patients with hemianopia following stroke.

## Methods

### *Trial design*

VISION was a randomised controlled, multicentre pilot trial with NHS research ethical approval (10/H1003/119). The trial protocol is reported elsewhere [13].

### *Participants*

Patients were eligible for inclusion if they met the criteria:

- a. 18 years of age or older;
- b. Best corrected visual acuity of 0.5 or better in each eye at distance;
- c. Stable homonymous hemianopia (partial or complete) induced by recent stroke, defined following WHO guidelines, present over 2 weeks (to exclude rapid recovery cases) but less than 26 weeks prior to randomisation;
- d. Refractive error within  $\pm 5$  Dioptries;
- e. Willing and able to give consent for the study;
- f. Prior to stroke able to read and understand English.

Patients were not eligible for inclusion if they were:

- a. unable to consent due to severe cognitive impairment;
- b. assessed to have ocular motility impairment and/or visual inattention in addition to the visual field impairment; or
- c. had pre-existent visual field impairment due to previous stroke.

Participants were recruited from stroke units based in 15 United Kingdom (UK)

National Health Service (NHS) Trusts. Potentially eligible participants were identified by stroke research nurses, and screened for inclusion by a local principal

investigator (a qualified orthoptist registered with the health and Care Professions Council, UK). Participants eligible for inclusion, and providing consent, attended for a baseline assessment, which included assessment and documentation of patient demographics, visual signs and symptoms, visual acuity measures, any additional ocular problems, comorbidity, severity of stroke and level of disability.

### ***Recruitment and randomisation***

Participants were individually randomised to one of three treatment groups using a secure (24-hour) web based randomisation programme. Randomisation lists were generated using block randomisation stratified by centre and degree of hemianopia (partial or complete) with treatment allocation ratio of 1:1:1. The local PI (orthoptist) obtained the treatment allocation and subsequently assigned the participant to the treatment arm.

### ***Interventions***

#### ***Treatment A: Fresnel prisms***

Participants were assessed and given sector Fresnel prisms of 40 prism dioptre strength on their glasses (or plain glasses if not already worn) [14]. Separate prism segments were used as a mechanical displacement to expand the upper and lower quadrants. Full fitting details are detailed in the protocol [13]. Participants were advised to wear the prisms for a minimum of 2 hours daily, for a minimum six weeks, from prism affixation; after this they could elect to continue treatment if wished.

#### ***Treatment B: Visual search training***

Participants were assessed and provided with visual search training. This comprised an A4 landscape card with horizontal and diagonal numbered circles radiating out

1  
2  
3  
4  
5  
6  
7 from a central fixation target. Full instructions for training are detailed in the protocol  
8 [13]. Participants were instructed to continually scan between the various targets for  
9 30 minutes daily for a minimum six weeks, after which they could elect to continue  
10 treatment if they wished. Participants were instructed on the search exercises to  
11 ensure their understanding of doing this training. In addition, printed instructions  
12 were provided with the visual training target cards.  
13  
14  
15  
16  
17

#### 18 *Treatment C: Control - Standard Care (Information Only)*

19  
20 Participants were given information leaflets from the UK Stroke Association and the  
21 UK Royal National Institute for the Blind (RNIB) about visual impairment following  
22 stroke.  
23  
24

25  
26  
27 Participants in all treatment groups received these information leaflets. Details of  
28 usage of the prisms and visual search training were collected by diaries, completed  
29 daily by participants.  
30  
31  
32

#### 33 **Outcomes**

34  
35  
36 Outcomes were assessed at baseline, 6, 12 and 26 weeks. The primary clinical  
37 outcome was relative change in visual field area (measured in degrees<sup>2</sup>) from  
38 baseline to 26 weeks and, based on this change, a sample size calculation for a  
39 future definitive trial. Secondary clinical outcomes, assessed by the orthoptist, were  
40 reading ability (speed and accuracy). Secondary clinical outcomes, reported by  
41 patients, were assessed through questionnaire booklets. [13]. Further key objectives  
42 of this pilot trial were to test the operationalisation of the intervention and the study  
43 outcome measures [13, 15].

57  
58  
59  
60

### Sample size calculation

A sample size calculation was estimated for repeated measures analysis of covariance [16], using the data generated on visual field assessment.

### Visual field assessment

A blinded qualified Orthoptist assessed visual field area. An Esterman strategy was used for quantitative visual field assessment with standard fixation monitoring strategies of fixation loss, false positive and false negative responses. This was done using either:

- The Esterman programme on Humphrey or Octopus perimetry,
- The III4e target on Goldmann with additional checks of static points in the central visual field.

A template for Goldmann perimetry was supplied for standardisation to match the Esterman strategy on Humphrey and Octopus perimetry. A binocular visual field was measured first followed by monocular assessment of the right and left eyes. Visual fields were performed without prisms in place in the *Fresnel prism* arm. Where it was not possible to use either of these methods then the standardised confrontation method was used. Whichever method used at baseline was repeated at every follow up visit. Where the confrontation method was used at baseline one of the above quantitative methods was used at the follow-up if possible in addition to repeating the confrontation method.

### Reading Ability

Reading ability, assessed using the Radner reading test, is reported as time taken to read (seconds) and number of incorrect words from the 14 word passage [17].

### **Patient Completed Outcome Measures**

Participants completed a questionnaire booklet containing the following outcome measures:

- a. Visual function questionnaire (VFQ 25-10) [18]
- b. Rivermead mobility index (RMI) [19]
- c. Nottingham extended activities of daily living assessment (NEADL) [20]
- d. Euro Qual [21]
  - i. 5D (EQ-5D)
  - ii. VAS score (EQ-VAS)
- e. Short Form -12 (SF-12) [22]
  - i. Physical component summary (PCS)
  - ii. Mental component summary (MCS)

### **Statistical Analysis**

There were insufficient data to carry out a formal power calculation to determine sample size for this trial, a sample size of 105 participants was considered sufficient to reach pilot objectives [13].

Outcome data were analysed according to the intention-to-treat principle. Safety analyses included all patients were randomised to and received treatment. A p-value of 0.05 is considered significant, however as this is a pilot study not powered to identify differences, results will be interpreted with caution. Additionally, rather than

1  
2  
3  
4  
5  
6  
7 adjust for multiplicity relevant results from other studies will be taken into account in  
8 the interpretation of results.  
9

10  
11  
12 The statistical analysis plan, written by the trial statisticians and agreed by other  
13 members of the trial management group (TMG) and independent oversight  
14 committees: data and safety monitoring committee (IDSMC) and the trial steering  
15 committee (TSC), prior to any comparative analyses together is available on request  
16 from the authors. No imputation methods were used for missing data and all patients  
17 who withdrew from the trial were encouraged to complete follow up.  
18  
19  
20  
21  
22  
23

24  
25  
26 All analyses were done with SAS software version 9.2. The primary feasibility  
27 outcome of sample size calculation was calculated for a repeated measures analysis  
28 of covariance [16]. Data collected from the trial were used to estimate the standard  
29 deviation, estimate of correlation and the loss to follow up rate for the main trial. All  
30 outcomes were summarised using descriptive statistics, split by treatment, at  
31 baseline and 26 week follow up. The primary efficacy outcome was relative change  
32 in area of visual field assessment (VFA), defined as the difference in VFA from  
33 baseline to 26 weeks follow up, divided by the maximum possible VFA score for  
34 each method, and was analysed using ANOVA, controlling for treatment. A  
35 sensitivity analysis was performed on the VFA using ANCOVA for the modal  
36 assessment method (see Outcomes – Visual Field Assessment). Patient reported  
37 secondary outcomes: VFQ 25-10; RMI; NEADL; EQ-VAS and SF-12: PCS and MCS,  
38 reported at 26 week follow up, were compared using analysis of covariance,  
39 controlling for treatment and baseline assessment. EQ-5D and Radner Reading  
40 Score were summarised using only descriptive statistics,

## Results

### *Recruitment and characteristics*

Recruitment and screening have been reported elsewhere [23]. In summary, 1171 patients were assessed for eligibility between 17<sup>th</sup> May 2011 and 9<sup>th</sup> September 2013. Of these, 993 patients (84.8%) did not meet the inclusion criteria, 91 patients declined to participate (7.8%) leaving 87 patients in the study (7.4%). The reasons for not being eligible and for refusing to consent were recorded and published [23]. In May 2012, the team noted that the proportion of eligible patients was lower than expected and this was slowing recruitment. Upon reviewing the accumulating recruitment data, the IDSMC recommended extending recruitment by one year and advised that the initial target sample size of 105 be reduced to 90 participants, of which 60 would be needed to complete the study. The TSC agreed with this proposal and the TMG actioned this amendment in June 2012. Figure 1 shows the cumulative recruitment graph, indicating *expected*, *revised expected* and *actual* recruitment by month.

At the end of the recruitment period, 27, 30 and 30 patients were randomised to *Fresnel prisms*, *Visual search training* and *standard care* respectively. Two patients (2/87, 2.3%) withdrew from data analysis and follow up; nine (9/87, 10.3%) from follow up only and five (5/87, 5.7%) were lost to follow up, of which four were from the standard arm (4/5, 80.0%). There was 24 (24/27, 88.9%), 25 (25/30, 83.3%) and 22 (22/30, 73.3%) patients in the *Fresnel prisms*, *Visual search training* and *standard care* respectively at 26 week follow up (see Figure 2).

1  
2  
3  
4  
5  
6  
7 Patient demographic and clinical characteristics at baseline are provided in Table 1  
8 and 2. There were no notable differences at baseline between three arms. The  
9 population consisted primarily of white (97.6%) males (69.4%) randomised, on  
10 average, 11 weeks post ischaemic (95.3%) stroke ([late recruitment relating to the](#)  
11 [requirement for stable, non-recovering hemianopia](#)). The infarct was mostly  
12 classified unilateral (43.5% left; 54.1% right).  
13

15  
16  
17  
18  
19

### 20 **Sample size outcome**

21  
22 Table 3 provides the sample size needed per arm to detect a minimally clinically  
23 important difference in visual field between per arm for a given power. Predictions  
24 are provided for three values of the minimally clinically important difference (200, 400  
25 and 600 degrees<sup>2</sup>) and for three levels of power (90%, 80% and 50%). 80% (70/87)  
26 of patients had full data at baseline and 26 weeks. Thus the required number of  
27 patients to be recruited was calculated as 1.25 times ( $=1/0.8$ ) the sample size shown  
28 in Table 3. Most recruiting sites used the Humphrey Static methods, with 33 in 70  
29 (47.1%) patients having their VFA assessed using this method. Computing the  
30 sample size in the same way for patients being assessed by this method only  
31 reduces the number required (Table 3).  
32  
33  
34  
35  
36

38  
39  
40  
41  
42

### 43 **Primary clinical outcome**

44  
45 There was some variability in baseline relative change in visual field area across  
46 treatment arm and by method (Table 4), particularly those methods used most  
47 frequently. For the *Humphrey Static Esterman* method, the mean baseline visual  
48 field area was one-third lower in the *standard care* arm (955.8 degrees) when  
49 compared to the *visual search training* or *Fresnel prism* arm; 1428.9 degrees and  
50  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6  
7 1382.5 degrees respectively. For the *Octopus Static Esterman* method, the mean  
8  
9 baseline visual field was 44.2% and 18.4% higher in the *standard care* arm when  
10  
11 compared to the *visual search training* and *Fresnel prism* arm respectively. These  
12  
13 differences can be explained by the large within-group variances of visual field  
14  
15 expected with a relatively low sample size per method of assessment and per arm.  
16  
17 The mean values of *relative* change in visual field area are given in Table 5, which  
18  
19 shows a non-significant average minimal increase in visual field at 26 weeks of 5%,  
20  
21 8% and 3.5% for *Fresnel prisms*, *Visual search training* and *standard care*,  
22  
23 respectively (p-values >5%, <5% and >5%, respectively).  
24  
25

### 26 **Secondary clinical outcomes**

27  
28 Change in functional activity was evaluated as a secondary analysis. Visual function  
29  
30 (using the VFQ 25-10) improved at 26 weeks in the *visual search training* arm (60  
31  
32 (SD19) to 68.4 (SD20) when compared to the *Fresnel Prisms* (68.5 (SD16.4) to 68.2  
33  
34 (18.4) and *standard care* arms ((63.7 (SD19.4) to 59.8 (SD22.7): Table 6, ANCOVA  
35  
36 p=0.05). No evidence of differences across arms were found for any of the other  
37  
38 secondary outcomes, including functional mobility (ANCOVA p=0.36, extended daily  
39  
40 level index (ANCOVA p=0.93), EQ-5D VAS score (ANCOVA p=0.60), change of  
41  
42 general health status (ANCOVA p=0.51), reading speed and reading accuracy.  
43  
44

### 45 **Compliance**

46  
47 There were 73 protocol deviations in 58 patients (68.2% overall: 77% in the *Fresnel*  
48  
49 *prism* arm, 93% in the *visual search* arm and 34.5% in the *standard care* arm). The  
50  
51 majority of deviations (n=41, 56.2%) related to lack of compliance in the intervention  
52  
53 arms (e.g., prism not worn a minimum of 2 hours daily for 6 weeks or visual  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6  
7 exercises not carried out for 30 minutes daily for 6 weeks). Compliance level was  
8 similar across the intervention arms. Patients in the Fresnel prisms arm wore the  
9 prisms during 27 days on average, and patients in the visual search training arm  
10 followed the visual search exercises 28 days on average. The protocol deviations in  
11 the standard group (n=10) were all related to timing and attendance at follow up  
12 visits.  
13  
14  
15  
16  
17

18 Eighteen patients (69.2%) in the *Fresnel prisms* arm experienced a total of 42  
19 adverse events of which 28 were classified as headache (Table 7). Two patients  
20 (6.7%) in the *visual search training* arm experienced seven adverse events (6  
21 fatigue, 1 headache). No adverse events were recorded for in the standard care arm.  
22  
23 Continuation of treatment was greater in the visual search arm than in the Fresnel  
24 prisms arm. In the visual search arm, 24 of 25 patients continued the intervention  
25 after 6 weeks, 21 of 25 after 12 weeks and 10 of 25 patients after 26 weeks. This  
26 was in comparison to 14 of 26 patients in the Fresnel prism arm after 6 weeks, 12 of  
27 23 after 12 weeks and 5 of 24 patients after 26 weeks.

### 37 **Discussion**

38  
39 Our primary clinical outcome measure was based on formal quantitative visual field  
40 assessment. Because of the multi-centre nature of the trial, a variety of visual field  
41 assessment methods were used as different hospitals had access to different  
42 perimeters. For future phase III trials using multiple visual field assessment methods,  
43 our sample size estimation is a maximum of 269 participants per arm for a minimum  
44 clinically important difference of 200 degree<sup>2</sup> of visual field area relative change.  
45  
46 Future trials using just one visual field assessment method require a sample size of  
47 a maximum of 132 participants for each arm.

4  
5  
6  
7 The primary clinical outcome measure for this trial was relative change in visual field  
8 area from baseline to 26 weeks. A Cochrane systematic review of interventions for  
9 post-stroke visual field loss concluded that, generally, interventions for homonymous  
10 hemianopia did not result in improvement of visual field [11]. Our results similarly  
11 showed minimal non-significant change in visual field across all 3 arms [of 5, 8 and](#)  
12 [3.5%. We considered that a change of 15% in visual field area would be clinically](#)  
13 [significant. The insignificant change in visual field was expected given the deliberate](#)  
14 [recruitment of denoting the](#) stable hemianopes ~~recruited~~ to the trial. [Other trials](#)  
15 [recruiting stable hemianopias also report no significant change to extent of visual](#)  
16 [field loss \[12,24\].](#)

17  
18  
19  
20  
21  
22  
23  
24  
25  
26 Published evidence relating to the effectiveness of interventions for post-stroke  
27 visual field loss is limited. Pollock and colleagues [11] concluded from their  
28 systematic review that compensatory scanning training interventions may be more  
29 beneficial than a placebo or control intervention at improving specific tasks. More  
30 recently, Aimola and colleagues [12] conducted a randomised controlled trial of  
31 visual exploration versus sham training and reported significant improvement in  
32 vision-related quality of life questionnaire scores following the intervention in  
33 comparison to sham training. They found no significant objective improvement noted  
34 in activity of daily living tasks. Our secondary clinical outcome measures included a  
35 range of questionnaires and indices to measure vision-related and health-related  
36 quality of life and activities of daily living. The only outcome measure to show a  
37 statistically significant change was vision-related quality of life (VFQ25/10).

38  
39  
40  
41  
42  
43  
44  
45  
46  
47  
48 Pollock and colleagues [11] found insufficient evidence to reach conclusions about  
49 the effectiveness of prisms; one more recent trial [24] compared real versus sham  
50 prism training. Their analysis of mobility questionnaire results showed no significant  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3  
4  
5  
6  
7 different in real versus sham prism use. Our data showed no significant difference in  
8 motility questionnaire results. However, we noted a range of adverse events related  
9 to treatment which were greatest for the Fresnel prism arm (69.2%) versus the visual  
10 search training arm (6.7%). There were no adverse events for standard care.

11  
12  
13  
14 Evaluation of recruitment and consent has been conducted for this trial and  
15 published previously [23]. We experienced greater recovery for hemianopia than  
16 previously reported in the literature and this should be taken into consideration when  
17 planning future trials with options to increase number of participating recruitment  
18 centres.

19  
20  
21  
22  
23  
24 Adverse events reported with Fresnel prism therapy included headaches, difficulties  
25 with navigation, double vision, optical glare/aberrations and visual confusion, similar  
26 to events reported in previous trials [14,24]. Headaches were the most common  
27 adverse event for Fresnel prisms. We acknowledge that headaches can also be a  
28 post-stroke symptom. However, in this trial, given that headaches were not a  
29 symptom reported by patients receiving standard care and uncommon in those  
30 receiving visual search training, they were attributed to the Fresnel prism treatment.

31  
32  
33  
34  
35  
36  
37 Given the extent and range of adverse events reported with prism wear, caution  
38 must be exercised if prescribing prism glasses as an intervention for homonymous  
39 hemianopia.

40  
41  
42  
43 Adverse events for visual search training were minimal and consisted of fatigue and  
44 headache. To help minimise these potential side effects training periods should be  
45 curtailed to shorter accumulated periods rather than one long training session.

46  
47  
48  
49 We used treatment diaries to capture patient use of interventions and extracted data  
50 from these and the case report forms as to whether patients voluntarily chose to  
51 continue their intervention beyond the minimum set treatment period of 6 weeks.  
52  
53

57  
58  
59  
60

1  
2  
3  
4  
5  
6  
7 More patients in the visual search arm voluntarily opted to continue their intervention  
8 than patients in the Fresnel prism arm.  
9

10 We noted 73 protocol deviations. For the intervention arms, these largely related to  
11 compliance with the treatment duration although no significant difference was found  
12  
13 in the level of compliance in both intervention arms. [In future trials participants could](#)  
14 [be encouraged to break up their treatment duration per day as also suggested for](#)  
15 [reduction of adverse events; for example of having 3 shorter blocks of treatment per](#)  
16 [day instead of only one large block of treatment.](#) For standard care most deviations  
17 related to follow-up visits taking place outside the time windows stipulated by the  
18 protocol. When planning future trials consideration should be given to regular  
19 telephone contact with patients to encourage on-going compliance with treatment  
20 and with timely reminders of upcoming review visits. [This may also help with](#)  
21 [reducing loss to follow-up cases.](#)

### 32 **Considerations**

33  
34 A potential limitation of the trial was the need to use different visual field perimeters,  
35 and perimetrists, across recruitment sites for the primary outcome visual field  
36 measurements. A consideration in future trials would be to use just one perimeter  
37 type or consider alternative primary outcome measures. Given that visual fields did  
38 not change significantly and requires patients to attend follow-up appointments at  
39 hospital eye clinics (a potential deterrent to trial participation) an appropriate  
40 alternative primary outcome measure may be a vision-related quality of life  
41 questionnaire such as the VFQ25 [although there are many other questionnaires to](#)  
42 [choose from dependent on whether a health-related or condition-specific](#)  
43 [questionnaire is required \[25\].](#)

57  
58  
59  
60

1  
2  
3  
4  
5  
6  
7 With regard to generalizability, as this is a pilot trial, results should be interpreted  
8 with caution [265]. Although we found a statistically significant improvement in  
9 VFQ25 for visual search training, our trial was not powered for this. Nonetheless, the  
10 clinical differences are encouraging and warrant further investigation.  
11  
12

13  
14 There remains insufficient evidence to reach conclusions about whether prisms are  
15 an effective intervention, and this study provides evidence of a high rate of adverse  
16 events associated with prism use. Clinicians with expert knowledge relating to prisms  
17 may consider their use for individual patients, but clinicians and patients both should  
18 be fully aware of potential adverse events and have a clear understanding relating to  
19 prism use.

## 28 **Conclusions**

29  
30 Our visual search training or Fresnel prism interventions for hemianopia produced  
31 minimal change in visual field area over the 26-week follow-up period. Visual search  
32 training produced a significant improvement in vision-related quality of life but not for  
33 other activity of daily living tasks. There were no significant improvements for any  
34 quality of life measure in our Fresnel prism arm. For the visual search arm, our  
35 participants reported a low percentage of adverse events, many continued with  
36 training and we found a significant change in quality of life. This must be interpreted  
37 with caution given our low sample size  
38  
39  
40  
41  
42  
43  
44

45 There are a number of considerations in relation to planning future trials. Assessing  
46 change in visual field which required formal visual field assessment using a variety of  
47 perimeter types. It would help to limit assessment to one method or alternatively  
48 remove this as an outcome measure. We experienced low recruitment initially but  
49

**Table 2. Baseline clinical characteristics**

Baseline Characteristic	Treatment			Total
	Fresnel prisms	Visual search training	Standard care	
Patients Randomised	26	30	29	85
Stroke onset (days from stroke to randomisation)				
Mean (SD)	75.5 (45.3)	73.8 (49.2)	81.2 (48.0)	76.9 (47.2)
Median (IQR)	64.5 (78.0)	69.0 (97.0)	67.0 (61.0)	67.0 (77.0)
Range	18.00 to 173.0	13.0 to 172.0	15.0 to 186.0	13.0 to 186.0
Stroke Type				
Ischaemic, n (%)	25 (96.2)	28 (93.3)	28 (96.6)	81 (95.3)
Haemorrhagic, n (%)	1 (3.8)	2 (6.7)	1 (3.4)	4 (4.7)
Side of infarct				
Left, n (%)	9 (34.6)	17 (56.7)	11 (37.9)	37 (43.5)
Right, n (%)	16 (61.5)	13 (43.3)	17 (58.6)	46 (54.1)
Bilateral, n (%)	1 (3.9)	0 (0.0)	1 (3.5)	2 (2.4)
Visual field assessment diagnosis:				
Homonymous hemianopia left partial, n (%)	8 (30.8)	5 (16.7)	8 (27.6)	21 (24.7)
Homonymous hemianopia right partial, n (%)	3 (11.5)	9 (30.0)	5 (17.2)	17 (20.0)
Homonymous hemianopia left complete, n (%)	9 (34.6)	8 (26.7)	10 (34.5)	27 (31.8)
Homonymous hemianopia right complete, n (%)	6 (23.1)	8 (26.7)	6 (20.7)	20 (23.5)
Bilateral hemianopia, n (%)	0 (0.0)	0 (0.0)	0 (0.0)	0 (0.0)
Barthel index score				
Mean (SD)	97.5 (5.5)	92.7 (11.9)	93.3 (14.7)	94.4 (11.6)
Median (IQR)	100.0 (0.0)	100.0 (15.0)	100.0 (5.0)	100.0 (5.0)
Range	80.0 to 100.0	65.0 to 100.0	45.0 to 100.0	45.0 to 100.0

**Table 3. Sample size estimation – total number of patients with complete follow up required per arm (significance level= 0.05)**

		Type II error ( $\beta$ )		
		0.1	0.2	0.5
Estimated using data from all visual field assessment methods				
Minimally clinically important difference	200 degrees <sup>2</sup>	269	203	98
	400 degrees <sup>2</sup>	68	51	25
	600 degrees <sup>2</sup>	30	23	11
Estimated using data from modal visual field assessment method: Humphrey				
Minimally clinically important difference	200 degrees <sup>2</sup>	132	100	48
	400 degrees <sup>2</sup>	33	25	12
	600 degrees <sup>2</sup>	15	12	6

## CONSORT 2010 checklist of information to include when reporting a randomised trial\*

Section/Topic	Item No	Checklist item	Reported on page No
<b>Title and abstract</b>			
	1a	Identification as a randomised trial in the title	1
	1b	Structured summary of trial design, methods, results, and conclusions (for specific guidance see CONSORT for abstracts)	2-3
<b>Introduction</b>			
Background and objectives	2a	Scientific background and explanation of rationale	3-4
	2b	Specific objectives or hypotheses	4
<b>Methods</b>			
Trial design	3a	Description of trial design (such as parallel, factorial) including allocation ratio	5
	3b	Important changes to methods after trial commencement (such as eligibility criteria), with reasons	n/a
Participants	4a	Eligibility criteria for participants	5
	4b	Settings and locations where the data were collected	5-6
Interventions	5	The interventions for each group with sufficient details to allow replication, including how and when they were actually administered	6-7
Outcomes	6a	Completely defined pre-specified primary and secondary outcome measures, including how and when they were assessed	7
	6b	Any changes to trial outcomes after the trial commenced, with reasons	n/a
Sample size	7a	How sample size was determined	8
	7b	When applicable, explanation of any interim analyses and stopping guidelines	n/a
Randomisation:			
Sequence generation	8a	Method used to generate the random allocation sequence	5
	8b	Type of randomisation; details of any restriction (such as blocking and block size)	5-6
Allocation concealment mechanism	9	Mechanism used to implement the random allocation sequence (such as sequentially numbered containers), describing any steps taken to conceal the sequence until interventions were assigned	5
Implementation	10	Who generated the random allocation sequence, who enrolled participants, and who assigned participants to interventions	5, 8
Blinding	11a	If done, who was blinded after assignment to interventions (for example, participants, care providers, those	

1			
2		assessing outcomes) and how	6
3			
4		11b If relevant, description of the similarity of interventions	n/a
5	Statistical methods	12a Statistical methods used to compare groups for primary and secondary outcomes	9
6		12b Methods for additional analyses, such as subgroup analyses and adjusted analyses	9-10
7			
8	<b>Results</b>		
9	Participant flow (a	13a For each group, the numbers of participants who were randomly assigned, received intended treatment, and	
10	diagram is strongly	were analysed for the primary outcome	11
11	recommended)	13b For each group, losses and exclusions after randomisation, together with reasons	11
12	Recruitment	14a Dates defining the periods of recruitment and follow-up	11
13		14b Why the trial ended or was stopped	11
14			
15	Baseline data	15 A table showing baseline demographic and clinical characteristics for each group	11
16	Numbers analysed	16 For each group, number of participants (denominator) included in each analysis and whether the analysis was	
17		by original assigned groups	11
18			
19	Outcomes and	17a For each primary and secondary outcome, results for each group, and the estimated effect size and its	
20	estimation	precision (such as 95% confidence interval)	12-13
21		17b For binary outcomes, presentation of both absolute and relative effect sizes is recommended	n/a
22	Ancillary analyses	18 Results of any other analyses performed, including subgroup analyses and adjusted analyses, distinguishing	
23		pre-specified from exploratory	12-13
24			
25	Harms	19 All important harms or unintended effects in each group (for specific guidance see CONSORT for harms)	13-14
26			
27	<b>Discussion</b>		
28	Limitations	20 Trial limitations, addressing sources of potential bias, imprecision, and, if relevant, multiplicity of analyses	17
29	Generalisability	21 Generalisability (external validity, applicability) of the trial findings	14-15
30	Interpretation	22 Interpretation consistent with results, balancing benefits and harms, and considering other relevant evidence	14-16
31			
32	<b>Other information</b>		
33	Registration	23 Registration number and name of trial registry	3
34	Protocol	24 Where the full trial protocol can be accessed, if available	4
35	Funding	25 Sources of funding and other support (such as supply of drugs), role of funders	3, 18
36			

37

38 \*We strongly recommend reading this statement in conjunction with the CONSORT 2010 Explanation and Elaboration for important clarifications on all the items. If relevant, we also

39 recommend reading CONSORT extensions for cluster randomised trials, non-inferiority and equivalence trials, non-pharmacological treatments, herbal interventions, and pragmatic trials.

40 Additional extensions are forthcoming: for those and for up to date references relevant to this checklist, see [www.consort-statement.org](http://www.consort-statement.org).

41
