# Global uniform estimate for the modulus of $2 D$ Ginzburg-Landau vortexless solutions with asymptotically infinite boundary energy 

Radu Ignat* Matthias Kurzke ${ }^{\dagger}$ Xavier Lamy ${ }^{\ddagger}$

November 13, 2019

#### Abstract

For $\varepsilon>0$, let $u_{\varepsilon}: \Omega \rightarrow \mathbb{R}^{2}$ be a solution of the Ginzburg-Landau system $$
-\Delta u_{\varepsilon}=\frac{1}{\varepsilon^{2}} u_{\varepsilon}\left(1-\left|u_{\varepsilon}\right|^{2}\right)
$$ in a Lipschitz bounded domain $\Omega$. In an energy regime that excludes interior vortices, we prove that $1-\left|u_{\varepsilon}\right|$ is uniformly estimated by a positive power of $\varepsilon$ globally in $\Omega$ provided that the energy of $u_{\varepsilon}$ at the boundary $\partial \Omega$ does not grow faster than $\varepsilon^{-\alpha}$ with $\alpha \in(0,1)$.

## 1 Introduction

Let $\Omega \subset \mathbb{R}^{2}$ be a Lipschitz bounded open connected set (not necessarily simply connected) with the unit outer normal and tangent vector fields $(\nu, \tau)$ defined a.e. on $\partial \Omega$ with

$$
\tau=\nu^{\perp}=\left(-\nu_{2}, \nu_{1}\right)
$$

so that $(\nu, \tau)$ forms an oriented frame a.e. on $\partial \Omega$. For every small $\varepsilon>0$, let $u_{\varepsilon}: \Omega \rightarrow \mathbb{R}^{2}$ be a solution of the Ginzburg-Landau system:

$$
\left\{\begin{align*}
-\Delta u_{\varepsilon} & =\frac{1}{\varepsilon^{2}} u_{\varepsilon}\left(1-\left|u_{\varepsilon}\right|^{2}\right) & & \text { in } \Omega  \tag{1}\\
u_{\varepsilon} & =g_{\varepsilon} & & \text { on } \partial \Omega
\end{align*}\right.
$$

with the boundary data $g_{\varepsilon}: \partial \Omega \rightarrow \mathbb{R}^{2}$. For the boundary energy

$$
\begin{equation*}
N_{\varepsilon}:=\int_{\partial \Omega} \frac{1}{2}\left|\partial_{\tau} g_{\varepsilon}\right|^{2}+\frac{1}{4 \varepsilon^{2}}\left(1-\left|g_{\varepsilon}\right|^{2}\right)^{2} d \mathcal{H}^{1} \tag{2}
\end{equation*}
$$

and the interior energy

$$
\begin{equation*}
M_{\varepsilon}:=\int_{\Omega} \frac{1}{2}\left|\nabla u_{\varepsilon}\right|^{2}+\frac{1}{4 \varepsilon^{2}}\left(1-\left|u_{\varepsilon}\right|^{2}\right)^{2} d x \tag{3}
\end{equation*}
$$

[^0]we assume that there exists a power $\alpha \in(0,1)$ such that ${ }^{1}$
\[

$$
\begin{equation*}
M_{\varepsilon} \leq \kappa|\log \varepsilon| \quad \text { and } \quad N_{\varepsilon} \ll \frac{1}{\varepsilon^{\alpha}} \quad \text { as } \quad \varepsilon \rightarrow 0 \tag{4}
\end{equation*}
$$

\]

for some small constant $\kappa>0$ depending on the Lipschitz regularity of $\Omega$. The first condition in (4) avoids nucleation of interior vortices of non-vanishing winding number (because the energetic cost of an interior vortex of non-zero winding number is of order $|\log \varepsilon|$, see the seminal book of Bethuel-Brezis-Hélein [4]). The second condition in (4) corresponds to an energetic regime avoiding the presence of boundary vortices: indeed, a transition of $g_{\varepsilon}$ between two opposite directions at the boundary on a distance $\varepsilon$ (the length scale of a vortex) has an energetic cost of order $\frac{1}{\varepsilon}$ (see Example 1 below). If $N_{\varepsilon} \lesssim \frac{1}{\varepsilon}$, then solutions $u_{\varepsilon}$ of (1) may have zeros on the boundary (see Proposition 3.

### 1.1 Main result

Our main result is the following global uniform estimate in the regime (4) for the convergence of $\left|u_{\varepsilon}\right|$ to 1 in $\Omega$, which means that $1-\left|u_{\varepsilon}\right|$ behaves as a positive power of $\varepsilon$.

Theorem 1 Let $\Omega \subset \mathbb{R}^{2}$ be a Lipschitz bounded domain. There exists a (small) constant $\kappa>0$ depending on the Lipschitz regularity of $\Omega$ such that for every solution $u_{\varepsilon}$ of (1) satisfying (4) for some $\alpha \in(0,1)$ we have the following global estimate ${ }^{2}$

$$
\sup _{\Omega}| | u_{\varepsilon}|-1| \leq C\left(\varepsilon^{1-}\left(1+N_{\varepsilon}+M_{\varepsilon}\right)\left(1+M_{\varepsilon}\right)^{\frac{1}{2}-}\right)^{\frac{1}{6}-} \quad \text { as } \quad \varepsilon \rightarrow 0
$$

for some constant $C>0$ depending only on the Lipschitz regularity $\square^{3}$ of $\Omega$. In particular, $g_{\varepsilon}$ has zero winding number on $\partial \Omega$, i.e. ${ }^{4}$

$$
\operatorname{deg}\left(g_{\varepsilon}, \partial \Omega\right):=\frac{1}{2 \pi} \int_{\partial \Omega} \frac{g_{\varepsilon}^{\perp}}{\left|g_{\varepsilon}\right|} \cdot \partial_{\tau}\left(\frac{g_{\varepsilon}}{\left|g_{\varepsilon}\right|}\right) d \mathcal{H}^{1}=0
$$

In particular, under the assumption of Theorem 1 , we deduce that

$$
\sup _{\Omega}| | u_{\varepsilon}|-1| \leq C \varepsilon^{\frac{1-\alpha}{6}-} \quad \text { as } \quad \varepsilon \rightarrow 0
$$

We believe that the power $\frac{1}{6}-$ of $\varepsilon$ in the above estimate is not optimal; moreover, the optimal power of $\varepsilon$ is expected to be $\leq \frac{1}{2}$ (see (9) below). The proof of Theorem 1 is done in several steps. In Section 2, we obtain a preliminary estimate of the uniform convergence of $\left|u_{\varepsilon}\right|$ to 1 , but at a much slower rate than the one claimed in Theorem 1. Thanks to this preliminary estimate, in Section 3, we will be able to use more efficiently the Ginzburg-Landau system (1) to deduce an improved rate for the convergence of $\left|u_{\varepsilon}\right|$ to 1 , first in the $L^{2}$-norm and then in the $L^{\infty}$-norm.

Remark 1 Our proof adapts with minor modifications to critical points of the energy

$$
\begin{equation*}
E_{\varepsilon}\left(u_{\varepsilon} ; \Omega\right):=\int_{\Omega} \frac{1}{2}\left|\nabla u_{\varepsilon}\right|^{2}+\frac{1}{4 \varepsilon^{2}} F\left(|u|^{2}\right) d x \tag{5}
\end{equation*}
$$

where $F \in C^{2}([0, \infty))$ satisfies $F \geq 0, F(1)=0$ and $(s-1) F^{\prime}(s) \geq c(1-s)^{2}$ for all $s \geq 0$ and some constant $c>0$. The typical example is $F(s)=(1-s)^{2}$.

[^1]
### 1.2 Optimality of our assumptions

Let us discuss the optimality of the assumption (4) in Theorem 1. First, the assumption on $M_{\varepsilon}$ in (4) is optimal: if the constant $\kappa$ is not small enough, then solutions $u_{\varepsilon}$ of (1) may vanish inside $\Omega$. Moreover, the threshold value of $\kappa$ at which this happens can be arbitrarily small depending on the Lipschitz regularity of the domain:

Proposition 2 For any $\theta_{0} \in(0, \pi)$ and any $\eta>0$ there exists a cone shape domain $\Omega$ of opening angle $\theta_{0}$, an exponent $\alpha \in(0,1)$ and a solution $u_{\varepsilon}$ of the Ginzburg-Landau system (1) such that for small $\varepsilon>0, u_{\varepsilon}\left(P_{\varepsilon}\right)=0$ for a degree-one vortex point $P_{\varepsilon} \in \Omega$ and (4) holds true for $\kappa=\frac{\theta_{0}}{2}+\eta$.

Second, the assumption on $N_{\varepsilon}$ in (4) is near-optimal in the following sense: if $N_{\varepsilon} \lesssim \frac{1}{\varepsilon}$, then a solution $u_{\varepsilon}$ of (1) may have zeros at the boundary of any Lipschitz domain $\Omega$.

Proposition 3 For any Lipschitz domain $\Omega$, there exists a solution $u_{\varepsilon}$ of the Ginzburg-Landau system (1) such that for small $\varepsilon>0, u_{\varepsilon}\left(x_{0}\right)=0$ for some $x_{0} \in \partial \Omega$, while $M_{\varepsilon} \lesssim 1$ and $N_{\varepsilon} \lesssim \frac{1}{\varepsilon}$.

We also point out that solutions of (1) with $M_{\varepsilon} \leq \kappa|\log \varepsilon|$ with small $\kappa$ may present an interior vortex with non-zero degree if the boundary energy is of order $\frac{1}{\varepsilon}$.

Proposition 4 For any smooth simply connected domain $\Omega$ and any small $\eta=\eta(\varepsilon)>0$, there exists a solution $u_{\eta}$ of the Ginzburg-Landau system (1) such that $\left|u_{\eta}\right|=1$ on $\partial \Omega$ and $\operatorname{deg}\left(u_{\eta}, \partial \Omega\right)=$ 1 (in particular, $u_{\eta}$ has a vortex on non-vanishing degree in $\Omega$ ), while $M_{\varepsilon} \lesssim\left(\frac{\eta}{\varepsilon}\right)^{2}|\log \eta|$ and $N_{\varepsilon} \lesssim \frac{1}{\eta}$. In particular,

- we can choose $\eta=\eta(\varepsilon)>0$ such that $M_{\varepsilon} \lesssim 1$ and $N_{\varepsilon} \lesssim \frac{|\log \varepsilon|^{1 / 2}}{\varepsilon}$;
- for every small $\kappa>0$, we can choose $\eta=\eta(\varepsilon, \kappa)>0$ such that $M_{\varepsilon} \leq \kappa|\log \varepsilon|$ and $N_{\varepsilon} \lesssim \frac{1}{\varepsilon}$.

Finally we remark that even for $\mathbb{S}^{1}$-valued boundary data with zero degree, if $N_{\varepsilon} \gg \frac{1}{\varepsilon}$ then minimizers may have bounded energy but modulus not uniformly close to 1 . (This is related to Example 1 in Section 1.4 below.)

Proposition 5 For any smooth bounded domain $\Omega$ and $\eta(\varepsilon) \ll \varepsilon \ll 1$, there exists $g_{\varepsilon} \in H^{1}\left(\partial \Omega ; \mathbb{S}^{1}\right)$ with $\operatorname{deg}\left(g_{\varepsilon}, \partial \Omega\right)=0$ an $b^{5} N_{\varepsilon} \sim \frac{1}{\eta(\varepsilon)}$, such that any minimizer $u_{\varepsilon}$ of $E_{\varepsilon}(\cdot ; \Omega)$ under the Dirichlet boundary condition $u_{\varepsilon}=g_{\varepsilon}$ on $\partial \Omega$ satisfies

$$
\sup _{\Omega}\left|1-\left|u_{\varepsilon}\right|^{2}\right| \geq \frac{1}{2} \quad \text { for } \varepsilon \ll 1
$$

while $M_{\varepsilon} \lesssim 1$.
The proofs of Propositions 2 to 5 can be found in Section 4 . The case $N_{\varepsilon} \ll \frac{1}{\varepsilon}$ (i.e., $\alpha=1$ in the regime (4)) remains open; in that case, we conjecture that our global estimate in Theorem 1 should still hold true, at least in smooth domains.

### 1.3 Related works

There is a huge literature on the analysis of solutions $u_{\varepsilon}$ of the Ginzburg-Landau system (1). Let us only mention some of them (and apologize for omitting many other important ones).

In the seminal paper (3), Bethuel, Brezis and Hélein studied the system (1) on a smooth simply connected domain $\Omega$ for minimizers $u_{\varepsilon}$ of the associated energy functional, with a fixed smooth boundary data $g_{\varepsilon}:=g$ such that $|g|=1$ on $\partial \Omega$ and $g$ is of zero winding number (so $N_{\varepsilon}, M_{\varepsilon}$ are of

[^2]order 1); they proved that $\left|\left|u_{\varepsilon}\right|-1\right|$ behaves as $\varepsilon^{2}$ globally in $\Omega$ and this rate is optimal. They also studied the case of non-fixed smooth boundary data $g_{\varepsilon}: \partial \Omega \rightarrow \mathbb{R}^{2}$ that is of zero winding number and has uniformly bounded energy $N_{\varepsilon} \lesssim 1$; then for minimizers $u_{\varepsilon}$, they deduced that $M_{\varepsilon} \lesssim 1$ and $\left|\left|u_{\varepsilon}\right|-1\right|$ behaves as $\varepsilon^{2}$ locally in $\Omega$. These results also hold for non-minimizing solutions if $u_{\varepsilon} \rightarrow u_{0}$ strongly in $H^{1}$ for some limit $u_{0}$, see [4, Remark A.1].

In [5], Bethuel, Orlandi and Smets considered solutions of (1) that need not be minimizing, without imposing any bounds on $M_{\varepsilon}$ or $N_{\varepsilon}$. They proved local estimates on $\left|\left|u_{\varepsilon}\right|-1\right|$, away from the boundary and from a vorticity set. In our setting, their results imply that $\left|\left|u_{\varepsilon}\right|-1\right|$ is of order at most $\varepsilon^{2(1-\beta)} M_{\varepsilon}$ in the region $\left\{x \in \Omega\right.$ : $\left.\operatorname{dist}(x, \partial \Omega) \geq \varepsilon^{\beta}\right\}$, for any $\beta \in(0,1)$, but do not provide a good uniform estimate up to the boundary.

In the present work we focus on obtaining, for solutions of (11) that need not be minimizing, precise uniform estimates on $\left|\left|u_{\varepsilon}\right|-1\right|$ which hold:

- up to the boundary $\partial \Omega$ of a general Lipschitz domain,
- and in a regime that goes beyond the restrictive uniform bound $N_{\varepsilon} \lesssim 1$.

Estimates up to the boundary of a rectangle were obtained in [7, Appendix] in the regime $M_{\varepsilon}, N_{\varepsilon} \ll|\log \varepsilon|$. There it was proved that $\left|\left|u_{\varepsilon}\right|-1\right|$ is of order at most $\left(\frac{1+N_{\varepsilon}+M_{\varepsilon}}{|\log \varepsilon|}\right)^{\frac{1}{6}-}$ globally in $\Omega$. In Section 2 we will follow the same approach in a general Lipschitz domain and under the less restrictive regime (4), as a first step towards the stronger estimate of Theorem 1 .

### 1.4 Motivation

The energy functional $E_{\varepsilon}$ is a simplified version of a model describing superconducting materials. We simply mention here that $\left|\left|u_{\varepsilon}\right|-1\right|$ measures how close the system is to a superconducting state, and refer the interested reader to the monographs 4, 16.

Another motivation comes from several studies of the pattern formation in thin ferromagnetic films [11, 7, 10, where one wishes to approximate $u_{\varepsilon}$ by $\mathbb{S}^{1}$-valued maps away from the vortices. In a vortexless region $\Omega$ (assume e.g. $\left.E_{\varepsilon}\left(u_{\varepsilon} ; \Omega\right) \ll|\log \varepsilon|\right)$, the idea introduced in [11] consists in finding a (squared, spherical etc.) grid $\mathcal{R}_{\varepsilon}$, each cell of the grid having the size $\sim \varepsilon^{\beta}$ with $\beta \in(0,1)$ (i.e., much larger than the length-scale of a vortex) such that the energy $E_{\varepsilon}\left(u_{\varepsilon} ; \mathcal{R}_{\varepsilon}\right)$ on the 1-dimensional grid $\mathcal{R}_{\varepsilon}$ is of order $E_{\varepsilon}\left(u_{\varepsilon} ; \Omega\right) / \varepsilon^{\beta}$. Then Theorem 1 implies that $\left|\left|u_{\varepsilon}\right|-1\right|$ behaves as a positive power of $\varepsilon$ in $\Omega$, and $v_{\varepsilon}=u_{\varepsilon} /\left|u_{\varepsilon}\right|$ is a "good" approximation of $u_{\varepsilon}$ (in terms of the $L^{2}$ norm, their global Jacobian etc., see [10]). In that context, we give the following consequence of Theorem 1 for a cell of the grid leading to a key estimate needed in [10] (only a weaker version of this key estimate was needed in [11, 7]):

Corollary 6 Let $\mathcal{C} \subset \mathbb{R}^{2}$ be a Lipschitz bounded domain. Let $\varepsilon>0, \beta \in(0,1)$ and $\mathcal{C}_{\varepsilon}:=\varepsilon^{\beta} \mathcal{C}$ be a cell of size $\varepsilon^{\beta}$. Assume that $u_{\varepsilon}$ is a solution of (1) in $\mathcal{C}_{\varepsilon}$ with

$$
\int_{\partial \mathcal{C}_{\varepsilon}} \frac{1}{2}\left|\partial_{\tau} g_{\varepsilon}\right|^{2}+\frac{1}{4 \varepsilon^{2}}\left(1-\left|g_{\varepsilon}\right|^{2}\right)^{2} d \mathcal{H}^{1} \ll \frac{|\log \varepsilon|}{\varepsilon^{\beta}}
$$

and

$$
\int_{\mathcal{C}_{\varepsilon}} \frac{1}{2}\left|\nabla u_{\varepsilon}\right|^{2}+\frac{1}{4 \varepsilon^{2}}\left(1-\left|u_{\varepsilon}\right|^{2}\right)^{2} d x \ll|\log \varepsilon|
$$

then

$$
\left|\left|u_{\varepsilon}\right|-1\right| \leq C \varepsilon^{\frac{1-\beta}{6}-} \quad \text { in } \quad \mathcal{C}_{\varepsilon}
$$

for some $C>0$ depending on the Lipschitz regularity of $\mathcal{C}$. In particular, $g_{\varepsilon}$ has zero winding number on $\mathcal{C}_{\varepsilon}$.

Proof. Denoting the rescaled map $\tilde{u}_{\tilde{\varepsilon}}(\tilde{x}):=u_{\varepsilon}\left(\varepsilon^{\beta} \tilde{x}\right)$ for $\tilde{x} \in \mathcal{C}$ with $\tilde{\varepsilon}:=\varepsilon^{1-\beta}$, then $\tilde{u}_{\tilde{\varepsilon}}$ satisfies the system (1) with the parameter $\tilde{\varepsilon}$ instead of $\varepsilon$ and the boundary energy, resp. interior energy of $\tilde{u}_{\tilde{\varepsilon}}$ on $\partial \mathcal{C}$, resp. in $\mathcal{C}$ are estimated by $N_{\tilde{\varepsilon}}, M_{\tilde{\varepsilon}} \ll|\log \tilde{\varepsilon}|$. By Theorem 1 , the conclusion follows.

As already hinted at, the regime (4) is motivated by the study of boundary vortices (see e.g. [14, 10]). In the absence of interior vortices, the first nontrivial example corresponds to a dipole of two compensating boundary vortices.

Example 1 Let $\Omega \subset \mathbb{R}^{2}$ be a bounded smooth domain containing the upper half unit ball, more precisely,

$$
\Omega \cap B(0,1)=\left\{x=\left(x_{1}, x_{2}\right) \in B(0,1): x_{2}>0\right\}
$$

where $B(0,1)$ is the unit ball centered at the origin. Let $\eta=\eta(\varepsilon) \in(0,1)$ be a parameter. Consider the boundary data $g_{\varepsilon}: \partial \Omega \rightarrow \mathbb{S}^{1}$ such that $g_{\varepsilon}(x)=e^{i \phi_{\varepsilon}}$ with

$$
\phi_{\varepsilon}(x)= \begin{cases}0 & \text { if } x \in \partial \Omega \backslash B(0, \eta)  \tag{6}\\ \pi\left(1-\frac{\left|x_{1}\right|}{\eta}\right) & \text { if } x=\left(x_{1}, x_{2}\right) \in \partial \Omega \cap B(0, \eta)\end{cases}
$$

(This is the prototype of a dipole of two boundary vortices corresponding of two consecutive transitions between opposite directions $\tau$ and $-\tau$ at the boundary at a distance $\eta$ ). We extend $\phi_{\varepsilon}$ to the entire domain $\Omega$ by setting $\phi_{\varepsilon}=0$ in $\Omega \backslash B(0, \eta)$ and $\phi_{\varepsilon}(x)=\pi\left(1-\frac{|x|}{\eta}\right)$ if $x \in \Omega \cap B(0, \eta)$. Then we compute that

$$
N_{\varepsilon}=\int_{\partial \Omega} \frac{1}{2}\left|\partial_{\tau} g_{\varepsilon}\right|^{2} d \mathcal{H}^{1} \lesssim \frac{1}{\eta}, \quad E_{\varepsilon}\left(e^{i \phi_{\varepsilon}} ; \Omega\right) \lesssim 1
$$

Therefore, if $u_{\varepsilon}$ is a minimizer of $E_{\varepsilon}(\cdot ; \Omega)$ under the Dirichlet boundary condition $u_{\varepsilon}=g_{\varepsilon}$ on $\partial \Omega$, we have that $E_{\varepsilon}\left(u_{\varepsilon} ; \Omega\right) \leq E_{\varepsilon}\left(e^{i \phi_{\varepsilon}} ; \Omega\right)$ so that 4 holds provided that $\frac{1}{\eta} \ll \frac{1}{\varepsilon^{\alpha}}$. In this case, Theorem 1 implies that $\left|u_{\varepsilon}\right|$ remains close to 1 as a positive power of $\varepsilon$, in particular, no interior vortices appear in $\Omega$. We highlight the fact that the regime $\varepsilon^{\alpha} \ll \eta$ with $\alpha \in(0,1)$ is essential in the above example for minimizers $u_{\varepsilon}$ to have modulus close to 1 uniformly. This scenario changes dramatically in the opposite regime $\eta \ll \varepsilon$ (see Proposition 5).

## Notations

In the sequel we will use the symbol $\lesssim$ to denote an inequality up to a multiplicative constant that depends only on the Lipschitz regularity of $\Omega$, that is, on $\left(\rho_{0}, \theta_{0}\right) \in(0, \infty) \times(0, \pi)$ such that for all $x \in \partial \Omega$ there is a cone of vertex $x$, radius $\rho_{0}$ and opening angle $\theta_{0}$ which is included in $\bar{\Omega}$, and the opposite cone is included in $\mathbb{R}^{2} \backslash \Omega$ (this is the uniform cone property, see e.g. [8, Theorem 1.2.2.2]). We also note that, thanks to the uniform cone property, the rectangle

$$
R=\left(-\frac{\rho_{0}}{2} \sin \frac{\theta_{0}}{2}, \frac{\rho_{0}}{2} \sin \frac{\theta_{0}}{2}\right) \times\left(-\rho_{0} \cos \frac{\theta_{0}}{2}, \rho_{0} \cos \frac{\theta_{0}}{2}\right)
$$

has the following property: for all $x \in \Omega$, there exists an angle $\gamma=\gamma(x) \in \mathbb{R}$ such that for all $t \in(0,1]$, the set

$$
\begin{equation*}
\mathcal{R}_{t}(x)=\left(x+t e^{i \gamma} R\right) \cap \Omega \text { is bi-Lipschitz homeomorphic to } t B \tag{7}
\end{equation*}
$$

where $B$ is the unit ball, and the Lipschitz constants of the homeomorphism and its inverse are bounded by a constant depending only on $\left(\rho_{0}, \theta_{0}\right)$. See Figure 1 below. (The angle $\gamma$ just serves to rotate the rectangle in order to align it with the cone; Figure 1 corresponds to $\gamma=0$.)

We recall that for $a \in \mathbb{R}$ we write $a+$ (resp. $a-$ ) to denote any real number strictly greater (resp. smaller) than $a$ but that can be chosen arbitrarily close to $a$. In inequalities involving such exponents, the constant will also depend on the distance of that number to $a$.

We write $B(x, r)$ for the ball centered at $x$ of radius $r$.

Figure 1: Cone property and rectangle $\mathcal{R}_{1}(x)$ at a boundary point $x \in \partial \Omega$

## 2 A-priori global uniform estimate of $\left|u_{\varepsilon}\right|$ in $\Omega$

The aim of this section is to prove the following weaker estimate of $\left|\left|u_{\varepsilon}\right|-1\right|$ in $\Omega$ :
Theorem 7 Let $\Omega \subset \mathbb{R}^{2}$ be a Lipschitz bounded domain. If $u_{\varepsilon}$ satisfies (1) and (4), then we have

$$
\sup _{\Omega}| | u_{\varepsilon}|-1| \lesssim\left(\frac{1+M_{\varepsilon}}{|\log \varepsilon|}\right)^{\frac{1}{6}-}
$$

In particular, if $\kappa$ is small enough in (4) then $\left|u_{\varepsilon}\right| \geq \frac{1}{2}$ in $\Omega$ as $\varepsilon \rightarrow 0$.
Theorem 7 is an improvement of [7, Theorem 6 in Appendix], where the boundary data satisfies the additional condition $\left|g_{\varepsilon}\right| \leq 1, \Omega$ is a square and $N_{\varepsilon} \ll|\log \varepsilon|$. We will follow the strategy in [7], generalizing to Lipschitz domains and general boundary data $g_{\varepsilon}: \partial \Omega \rightarrow \mathbb{R}^{2}$ with $N_{\varepsilon}$ satisfying the wider regime (4). The proof of Theorem 7 is divided into three parts:

Part 1 of the proof of Theorem 7 . We prove the following upper bound of $\left|u_{\varepsilon}\right|$ in $\Omega$ :

$$
\begin{equation*}
\left\|u_{\varepsilon}\right\|_{L^{\infty}(\Omega)}-1 \lesssim \sqrt{\varepsilon N_{\varepsilon}} \tag{8}
\end{equation*}
$$

For that, we start by denoting $\zeta=\left(1-\left|g_{\varepsilon}\right|\right)^{2}$ on $\partial \Omega$. The Cauchy-Schwarz inequality yields: ${ }^{6}$

$$
\frac{1}{2}\left|\partial_{\tau} g_{\varepsilon}\right|^{2}+\frac{1}{4 \varepsilon^{2}}\left(1-\left|g_{\varepsilon}\right|^{2}\right)^{2} \geq \frac{1}{8 \varepsilon^{2}} \zeta+\left(\frac{1}{8 \varepsilon^{2}} \zeta+\frac{1}{2}\left|\partial_{\tau}\right| g_{\varepsilon}| |^{2}\right) \geq \frac{1}{8 \varepsilon^{2}} \zeta+\frac{1}{4 \varepsilon}\left|\partial_{\tau} \zeta\right| \quad \text { on } \partial \Omega
$$

Using the embedding $W^{1,1}(\partial \Omega) \subset L^{\infty}(\partial \Omega)$, as $\mathcal{H}^{1}(\partial \Omega) \geq \varepsilon$, we deduce by $(2)$ :

$$
N_{\varepsilon}=\int_{\partial \Omega} \frac{1}{2}\left|\partial_{\tau} g_{\varepsilon}\right|^{2}+\frac{1}{4 \varepsilon^{2}}\left(1-\left|g_{\varepsilon}\right|^{2}\right)^{2} d \mathcal{H}^{1} \gtrsim \frac{1}{\varepsilon}\|\zeta\|_{L^{\infty}(\partial \Omega)}, \quad \text { as } \quad \varepsilon \rightarrow 0
$$

so that

$$
\begin{equation*}
\delta_{\varepsilon}:=\left\|\left|g_{\varepsilon}\right|-1\right\|_{L^{\infty}(\partial \Omega)} \lesssim \sqrt{\varepsilon N_{\varepsilon}} \tag{9}
\end{equation*}
$$

[^3]Let $\tilde{\rho}_{\varepsilon}=1-\left|u_{\varepsilon}\right|^{2}$ in $\Omega$. Then (1) implies that

$$
-\Delta \tilde{\rho}_{\varepsilon}+\frac{2}{\varepsilon^{2}}\left|u_{\varepsilon}\right|^{2} \tilde{\rho}_{\varepsilon}=2\left|\nabla u_{\varepsilon}\right|^{2} \geq 0 \quad \text { in } \quad \Omega
$$

and $\tilde{\rho}_{\varepsilon}=1-\left|g_{\varepsilon}\right|^{2} \geq 1-\left(1+\delta_{\varepsilon}\right)^{2}$ on $\partial \Omega$. Thus, the maximum principle ${ }^{7}$ implies that $\tilde{\rho}_{\varepsilon} \geq 1-\left(1+\delta_{\varepsilon}\right)^{2}$ in $\Omega$, i.e., $\left|u_{\varepsilon}\right| \leq 1+\delta_{\varepsilon}$ in $\Omega$ yielding (8) by (9).

Part 2 of the proof of Theorem 7 . We estimate a Hölder seminorm for $u_{\varepsilon}$.
Lemma 8 Let $\Omega \subset \mathbb{R}^{2}$ be a Lipschitz bounded domain. If $u_{\varepsilon}$ satisfies (1) and (4), then ${ }^{8}$

$$
\left|u_{\varepsilon}(x)-u_{\varepsilon}(y)\right| \leq C\left(\frac{|x-y|}{\varepsilon}\right)^{\frac{1}{2}-} \quad \forall x, y \in \Omega
$$

where $C>0$ depends only on the Lipschitz regularity of $\Omega$.
Remark 2 In general, we don't have that $\left\|\nabla u_{\varepsilon}\right\|_{L^{\infty}(\Omega)} \leq \frac{C}{\varepsilon}$ because this estimate can be violated by the boundary condition $g_{\varepsilon}$ on $\partial \Omega$. But since $g_{\varepsilon}$ belongs to $H^{1}(\partial \Omega)$ that embeds into the Hölder space $C^{0, \frac{1}{2}}(\partial \Omega)$, we can deduce an appropriate estimate of a Hölder seminorm for $u_{\varepsilon}$ in $\Omega$.

Proof of Lemma 8. Consider the rescaled map $\hat{u}(\hat{x})=u_{\varepsilon}(\varepsilon \hat{x})$ defined for $\hat{x} \in \Omega_{\varepsilon}=\varepsilon^{-1} \Omega$. (The map $\hat{u}$ depends on $\varepsilon$, we omit this dependence to simplify notation.) This map solves

$$
\left\{\begin{aligned}
-\Delta \hat{u} & =\left(1-|\hat{u}|^{2}\right) \hat{u} & & \text { in } \Omega_{\varepsilon} \\
\hat{u} & =\hat{g} & & \text { on } \partial \Omega_{\varepsilon}
\end{aligned}\right.
$$

where $\hat{g}(\hat{x})=g_{\varepsilon}(\varepsilon \hat{x})$ for $\hat{x} \in \partial \Omega_{\varepsilon}$. We fix $x_{0} \in \Omega_{\varepsilon}$ and consider the Lipschitz domain

$$
\mathcal{R}=\mathcal{R}\left(x_{0}\right)=\frac{1}{\varepsilon}\left(\left(\varepsilon x_{0}+\varepsilon e^{i \gamma\left(\varepsilon x_{0}\right)} R\right) \cap \Omega\right)
$$

which is bi-Lipschitz homeomorphic to the unit ball $B$, with Lipschitz bounds uniform in $\varepsilon$ and $x_{0}$ and depending only on the Lipschitz regularity of $\Omega$, thanks to the definition of $R$, see (7). Since $|\hat{g}| \leq 1+\delta_{\varepsilon} \leq 2$ on $\partial \Omega_{\varepsilon}\left(\right.$ by (9p) and $|\hat{u}| \leq 1+\delta_{\varepsilon} \leq 2$ in $\Omega_{\varepsilon}($ by (8)) as $\varepsilon \rightarrow 0$, elliptic estimates in Lipschitz domains (see e.g. [12, 17, and [13, Section VI] for the theory of traces) yield

$$
\|\hat{u}\|_{H^{\frac{3}{2}-}(\mathcal{R})} \lesssim 1+\left\|\partial_{\tau} \hat{g}\right\|_{L^{2}\left(\partial \Omega_{\varepsilon}\right)} .
$$

The constant depends only on the Lipschitz regularity of the domain $\mathcal{R}$ (see e.g. the proof of Theorem 2 in [17]), and is therefore bounded independently of $x_{0} \in \Omega_{\varepsilon}$ and $\varepsilon \in(0,1]$. By Sobolev embedding we deduce that

$$
\|\hat{u}\|_{C^{0, \frac{1}{2}-}(\mathcal{R})} \lesssim 1+\left\|\partial_{\tau} \hat{g}\right\|_{L^{2}\left(\partial \Omega_{\varepsilon}\right)} \lesssim 1+\left(\varepsilon N_{\varepsilon}\right)^{\frac{1}{2}}
$$

The constant in the Sobolev imbedding depends only on the Lipschitz regularity of $\Omega$, since the imbedding inequalities $\|v\|_{L^{4-}(B)} \lesssim\|v\|_{H^{\frac{1}{2}-}(B)}$ and $\|v\|_{C^{0, \frac{1}{2}-}(B)} \lesssim\|v\|_{W^{1,4-}(B)}$ are valid on the unit ball $B \subset \mathbb{R}^{2}$ and behave well under composition by a bi-Lipschitz homeomorphism. Since any

[^4]two points $x, y \in \Omega_{\varepsilon}$ which are close enough are contained in a domain $\mathcal{R}\left(x_{0}\right)$ for some $x_{0} \in \Omega_{\varepsilon}$, recalling once more that $|\hat{u}| \leq 2$ in $\Omega_{\varepsilon}$ (by (8)) we infer
$$
\|\hat{u}\|_{C^{0, \frac{1}{2}-}\left(\Omega_{\varepsilon}\right)} \lesssim 1+\left(\varepsilon N_{\varepsilon}\right)^{\frac{1}{2}} \lesssim 1 \quad \text { as } \quad \varepsilon \rightarrow 0
$$

The last inequality is due to our assumption (4). The conclusion follows by scaling back to $u_{\varepsilon}(x)=\hat{u}\left(\varepsilon^{-1} x\right)$.

Part 3 of the proof of Theorem 7 . We start by estimating the normal derivative of $u_{\varepsilon}$ at the boundary $\partial \Omega$ :

Lemma 9 Let $\Omega \subset \mathbb{R}^{2}$ be a Lipschitz bounded domain. If $u_{\varepsilon}$ satisfies (1), then we have ${ }^{9}$

$$
\int_{\partial \Omega}\left|\partial_{\nu} u_{\varepsilon}\right|^{2} d \mathcal{H}^{1} \lesssim M_{\varepsilon}+N_{\varepsilon}
$$

Proof of Lemma 9. We use the Pohozaev identity for $u_{\varepsilon}$ in the spirit of [3, Proposition 3], the only difference is to adapt that result to the setting of Lipschitz domains $\Omega$. More precisely, we consider a map $V: \Omega \rightarrow \mathbb{R}^{2}$ that is $C^{1}$ in the closed domain $\bar{\Omega}$ and such that $V \cdot \nu \geq a>0$ on $\partial \Omega$ for some $a>0$ depending only on the Lipschitz regularity of $\Omega$ (see e.g. [8, Lemma 1.5.1.9]). Multiplying the equation (1) by $(V(x) \cdot \nabla) u_{\varepsilon}$ and integrating by parts, as $V \in C^{1}(\bar{\Omega})$, we deduce by (2) and (3):

$$
\begin{align*}
\left|\frac{1}{\varepsilon^{2}} \int_{\Omega} u_{\varepsilon}\left(1-\left|u_{\varepsilon}\right|^{2}\right) \cdot(V(x) \cdot \nabla) u_{\varepsilon} d x\right|=\mid & \frac{1}{4 \varepsilon^{2}} \int_{\Omega} \nabla \cdot V\left(1-\left|u_{\varepsilon}\right|^{2}\right)^{2} d x \\
& \left.-\frac{1}{4 \varepsilon^{2}} \int_{\partial \Omega} V(x) \cdot \nu\left(1-\left|g_{\varepsilon}\right|^{2}\right)^{2} d \mathcal{H}^{1} \right\rvert\, \lesssim M_{\varepsilon}+N_{\varepsilon},  \tag{10}\\
\int_{\Omega} \Delta u_{\varepsilon} \cdot(V(x) \cdot \nabla) u_{\varepsilon} d x= & \int_{\partial \Omega}\left((\nu \cdot \nabla) u_{\varepsilon} \cdot(V \cdot \nabla) u_{\varepsilon}-\frac{1}{2} V \cdot \nu\left|\nabla u_{\varepsilon}\right|^{2}\right) d \mathcal{H}^{1}  \tag{11}\\
& +\int_{\Omega}\left(\frac{1}{2} \nabla \cdot V\left|\nabla u_{\varepsilon}\right|^{2}-\sum_{j=1,2} \partial_{j} u_{\varepsilon} \cdot\left(\partial_{j} V \cdot \nabla\right) u_{\varepsilon}\right) d x
\end{align*}
$$

For $x \in \partial \Omega$, we decompose $V=s(x) \nu+t(x) \tau$ where $s, t \in L^{\infty}(\partial \Omega), s(x)=V \cdot \nu \geq a>0$ for a.e. $x \in \partial \Omega$, and $\nabla u_{\varepsilon}=\nu \otimes \partial_{\nu} u_{\varepsilon}+\tau \otimes \partial_{\tau} g_{\varepsilon}$ on $\partial \Omega$. By (11), (22), (3), (10) and (11), as $V \in C^{1}(\bar{\Omega})$, we conclude by Young's inequality:

$$
M_{\varepsilon}+N_{\varepsilon} \gtrsim \int_{\partial \Omega}\left(\frac{s(x)}{2}\left|\partial_{\nu} u_{\varepsilon}\right|^{2}-\frac{s(x)}{2}\left|\partial_{\tau} g_{\varepsilon}\right|^{2}+t(x) \partial_{\nu} u_{\varepsilon} \cdot \partial_{\tau} g_{\varepsilon}\right) d \mathcal{H}^{1} \gtrsim \int_{\partial \Omega}\left|\partial_{\nu} u_{\varepsilon}\right|^{2} d \mathcal{H}^{1}-N_{\varepsilon}
$$

We use Lemma 9 to prove the following estimate of the potential energy in small balls (of radius $\ll \varepsilon^{\alpha}$ ). To simplify notation, we denote the energy density by

$$
e_{\varepsilon}\left(u_{\varepsilon}\right):=\frac{1}{2}\left|\nabla u_{\varepsilon}\right|^{2}+\frac{1}{4 \varepsilon^{2}}\left(1-\left|u_{\varepsilon}\right|^{2}\right)^{2}, \quad u_{\varepsilon}: \Omega \rightarrow \mathbb{R}^{2} .
$$

(In the context of the energy (5), only the assumption $F \in C^{1}$ is needed for the following estimate).

[^5]Lemma 10 Let $\Omega \subset \mathbb{R}^{2}$ be a Lipschitz bounded domain and $u_{\varepsilon}$ be a solution of 11 in the regime (4). Fix $1>\alpha_{1}>\alpha_{2}>\alpha>0$. There exists $C \geq 1$ such that for every $x_{0} \in \Omega$, we can find $r_{0}=r_{0}\left(x_{0}\right) \in\left(\varepsilon^{\alpha_{1}}, \varepsilon^{\alpha_{2}}\right)$ such that

$$
\begin{equation*}
\int_{\partial\left(B\left(x_{0}, r_{0}\right) \cap \Omega\right)} e_{\varepsilon}\left(u_{\varepsilon}\right) d \mathcal{H}^{1} \leq \frac{C\left(1+M_{\varepsilon}\right)}{r_{0}|\log \varepsilon|} \tag{12}
\end{equation*}
$$

for every $\varepsilon \leq \varepsilon_{0}$ with $\varepsilon_{0}=\varepsilon_{0}\left(\alpha_{2}, \alpha\right)>0$. Moreover, we have that

$$
\begin{equation*}
\frac{1}{\varepsilon^{2}} \int_{B\left(x_{0}, r_{0}\right) \cap \Omega}\left(1-\left|u_{\varepsilon}\right|^{2}\right)^{2} d x \leq \frac{\tilde{C}\left(1+M_{\varepsilon}\right)}{|\log \varepsilon|} \tag{13}
\end{equation*}
$$

for some $\tilde{C} \geq 1$.
Proof of Lemma 10, We distinguish two steps:
Step 1. Proof of (12). Assume by contradiction that for every $C \geq 1$ there exists $x \in \Omega$ such that for every $r \in\left(\varepsilon^{\alpha_{1}}, \varepsilon^{\alpha_{2}}\right)$ we have

$$
\int_{\partial(B(x, r) \cap \Omega)} e_{\varepsilon}\left(u_{\varepsilon}\right) d \mathcal{H}^{1} \geq \frac{C\left(1+M_{\varepsilon}\right)}{r|\log \varepsilon|}
$$

Since $N_{\varepsilon} \varepsilon^{\alpha} \ll 1$, by (2) and Lemma 9, there exists $c_{1}>0$ such that

$$
\int_{\partial \Omega} e_{\varepsilon}\left(u_{\varepsilon}\right) d \mathcal{H}^{1} \leq c_{1}\left(M_{\varepsilon}+N_{\varepsilon}\right) \leq \frac{1+M_{\varepsilon}}{2 \varepsilon^{\alpha_{2}}|\log \varepsilon|} \leq \frac{C\left(1+M_{\varepsilon}\right)}{2 r|\log \varepsilon|}, \quad \forall r \in\left(\varepsilon^{\alpha_{1}}, \varepsilon^{\alpha_{2}}\right)
$$

for every $\varepsilon \leq \varepsilon_{0}$ (with $\varepsilon_{0}>0$ depending on $\alpha_{2}$ and $\alpha$ ). Therefore, we deduce that

$$
\int_{\partial B(x, r) \cap \Omega} e_{\varepsilon}\left(u_{\varepsilon}\right) d \mathcal{H}^{1} \geq \frac{C\left(1+M_{\varepsilon}\right)}{2 r|\log \varepsilon|}
$$

Integrating in $r \in\left(\varepsilon^{\alpha_{1}}, \varepsilon^{\alpha_{2}}\right)$, we obtain by (3):
$M_{\varepsilon}=\int_{\Omega} e_{\varepsilon}\left(u_{\varepsilon}\right) d x \geq \int_{B\left(x, \varepsilon^{\alpha_{2}}\right) \cap \Omega} e_{\varepsilon}\left(u_{\varepsilon}\right) d x \geq \int_{\varepsilon^{\alpha_{1}}}^{\varepsilon^{\alpha_{2}}} d r \int_{\partial B(x, r) \cap \Omega} e_{\varepsilon}\left(u_{\varepsilon}\right) d \mathcal{H}^{1} \geq \frac{C\left(\alpha_{1}-\alpha_{2}\right)\left(1+M_{\varepsilon}\right)}{2}$
which is a contradiction with the fact that $C$ can be arbitrary large.
Step 2. Proof of 13 . Let $\nu$ be the outer unit normal vector at the boundary of the domain

$$
\mathcal{D}:=B\left(x_{0}, r_{0}\right) \cap \Omega
$$

As in the proof of Lemma 9, we use the Pohozaev identity for the solution $u_{\varepsilon}$ of (1). Indeed, multiplying the equation by $\left(x-x_{0}\right) \cdot \nabla u_{\varepsilon}$ and integrating by parts, we deduce:

$$
\begin{array}{rl}
\int_{\mathcal{D}}-\Delta u_{\varepsilon} \cdot\left(\left(x-x_{0}\right) \cdot \nabla u_{\varepsilon}\right) d x & =\int_{\partial \mathcal{D}}( \\
2 & 1 \\
\frac{1}{\varepsilon^{2}} \int_{\mathcal{D}} u_{\varepsilon}\left(1-\left|u_{\varepsilon}\right|^{2}\right) \cdot\left(\left(x-x_{0}\right) \cdot \nabla u_{\varepsilon}\right) d x= & \frac{1}{2 \varepsilon^{2}} \int_{\mathcal{D}}\left(1-\left|u_{\varepsilon}\right|^{2}\right)^{2} d x \\
& -\frac{1}{4 \varepsilon^{2}} \int_{\partial \mathcal{D}}\left(x-x_{0}\right) \cdot \nu\left(1-\left|u_{\varepsilon}\right|^{2}\right)^{2} d \mathcal{H}^{1}
\end{array}
$$

Since $\left|x-x_{0}\right| \leq r_{0}$ on $\partial \mathcal{D}$, by 12 , we deduce that 13 holds true.
The conclusion of Theorem 7 comes from the following result:

Lemma 11 Let $\Omega \subset \mathbb{R}^{2}$ be a Lipschitz bounded domain. If $u_{\varepsilon}$ satisfies (11) and (4), then we have 10

$$
\left\|\left|u_{\varepsilon}\right|^{2}-1\right\|_{L^{\infty}(\Omega)} \lesssim\left(\frac{1+M_{\varepsilon}}{|\log \varepsilon|}\right)^{\frac{1}{6}-}
$$

Proof. Let $x_{0} \in \Omega$ and set $1>A \geq 0$ such that

$$
4 C A^{\frac{1}{2}-}=\frac{\left|1-\left|u_{\varepsilon}\left(x_{0}\right)\right|^{2}\right|}{2}
$$

where $C \geq 1$ is given by Lemma 8. By Lemma 8, we obtain for any $y \in B\left(x_{0}, A \varepsilon\right) \cap \Omega$

$$
\left|1-\left|u_{\varepsilon}(y)\right|^{2}\right| \geq\left|1-\left|u_{\varepsilon}\left(x_{0}\right)\right|^{2}\right|-4 C A^{\frac{1}{2}-}=\frac{\left|1-\left|u_{\varepsilon}\left(x_{0}\right)\right|^{2}\right|}{2}
$$

as $\left|u_{\varepsilon}(y)\right|+\left|u_{\varepsilon}\left(x_{0}\right)\right| \leq 4$. Hence, for small $\varepsilon$,

$$
\begin{align*}
\int_{B\left(x_{0}, A \varepsilon\right) \cap \Omega}\left(1-\left|u_{\varepsilon}(y)\right|^{2}\right)^{2} d y & \geq C(\Omega) A^{2} \varepsilon^{2}\left(1-\left|u_{\varepsilon}\left(x_{0}\right)\right|^{2}\right)^{2}  \tag{14}\\
& \geq \tilde{C}(\Omega) \varepsilon^{2}\left(1-\left|u_{\varepsilon}\left(x_{0}\right)\right|^{2}\right)^{6+}
\end{align*}
$$

where $C(\Omega), \tilde{C}(\Omega)>0$. We have that $B\left(x_{0}, A \varepsilon\right) \subset B\left(x_{0}, r_{0}\right)$ for $\varepsilon \leq \varepsilon_{0}$ with $\varepsilon_{0}$ depending only on $\alpha_{1}$ in Lemma 10 Thus, by 13), we obtain

$$
\left(1-\left|u_{\varepsilon}\left(x_{0}\right)\right|^{2}\right)^{6+} \leq \hat{C} \frac{1+M_{\varepsilon}}{|\log \varepsilon|}
$$

and the conclusion follows.

## 3 Proof of Theorem 1

The main idea is to improve the convergence of $\left|u_{\varepsilon}\right|$ to 1 locally in $L^{2}$-norm; this involves improving the local estimate of the potential energy (13) to a positive power of $\varepsilon$ and then the argument in Lemma 11 yields the conclusion (i.e., the desired estimate in $L^{\infty}$ _norm of $\left|u_{\varepsilon}\right|-1$ in our main result).

Let $x_{0} \in \Omega$ and $\varepsilon>0$. By Fubini's theorem we may choose $t \in[1 / 2,1]$ such that the domain

$$
\begin{equation*}
\mathcal{R}=\mathcal{R}_{t}\left(x_{0}\right) \tag{15}
\end{equation*}
$$

defined in (7) satisfies

$$
\begin{equation*}
\int_{\partial \mathcal{R} \cap \Omega} \frac{1}{2}\left|\nabla u_{\varepsilon}\right|^{2}+\frac{1}{4 \varepsilon^{2}}\left(1-\left|u_{\varepsilon}\right|^{2}\right)^{2} d \mathcal{H}^{1} \lesssim M_{\varepsilon} \tag{16}
\end{equation*}
$$

Recall that $\mathcal{R}$ is bi-Lipschitz homeomorphic to the unit ball $B$, in particular it is simply connected. Moreover by Theorem 7 if $\kappa$ is small enough then $u_{\varepsilon}$ does not vanish. So we may write

$$
u_{\varepsilon}=\rho_{\varepsilon} e^{i \varphi_{\varepsilon}} \quad \text { in } \mathcal{R}
$$

with $\rho_{\varepsilon}, \varphi_{\varepsilon} \in H^{1}(\mathcal{R})$ (moreover, $\rho_{\varepsilon}^{2}$ and $\varphi_{\varepsilon}$ are smooth in $\mathcal{R}$ as $u_{\varepsilon}$ is smooth by standard elliptic regularity). The system (1) writes in terms of $\rho_{\varepsilon}$ and $\varphi_{\varepsilon}$ :

$$
\begin{cases}-\Delta \rho_{\varepsilon}+\rho_{\varepsilon}\left|\nabla \varphi_{\varepsilon}\right|^{2}=\frac{1}{\varepsilon^{2}} \rho_{\varepsilon}\left(1-\rho_{\varepsilon}^{2}\right) & \text { in } \mathcal{R} .  \tag{17}\\ \nabla \cdot\left(\rho_{\varepsilon}^{2} \nabla \varphi_{\varepsilon}\right)=0\end{cases}
$$

[^6]Step 1. We prove the following estimate ${ }^{11}$ of $\nabla \varphi_{\varepsilon}$ in $L^{q}(\mathcal{R})$, where $q=4-$ :

$$
\begin{equation*}
\left\|\nabla \varphi_{\varepsilon}\right\|_{L^{q}(\mathcal{R})} \lesssim 1+N_{\varepsilon} \varepsilon^{\frac{1}{2}}+M_{\varepsilon}^{\frac{1}{2}} . \tag{18}
\end{equation*}
$$

Indeed, by (2), (9), Lemma 9 and (16), we note that

$$
\begin{align*}
\int_{\partial \Omega \cap \mathcal{R}}\left|\nabla \varphi_{\varepsilon}\right|^{2} d \mathcal{H}^{1} & \lesssim \int_{\partial \Omega}\left|\nabla u_{\varepsilon}\right|^{2} d \mathcal{H}^{1} \lesssim N_{\varepsilon}+M_{\varepsilon}  \tag{19}\\
\text { and } \int_{\Omega \cap \partial \mathcal{R}}\left|\nabla \varphi_{\varepsilon}\right|^{2} d \mathcal{H}^{1} & \lesssim \int_{\partial \mathcal{R} \cap \Omega}\left|\nabla u_{\varepsilon}\right|^{2} d \mathcal{H}^{1} \lesssim M_{\varepsilon} .
\end{align*}
$$

Therefore, by the Poincaré-Wirtinger inequality, up to adding a constant to $\varphi_{\varepsilon}$, we can assume that

$$
\begin{equation*}
\left\|\varphi_{\varepsilon}\right\|_{H^{1}(\partial \mathcal{R})} \lesssim 1+N_{\varepsilon}^{\frac{1}{2}}+M_{\varepsilon}^{\frac{1}{2}} \tag{20}
\end{equation*}
$$

By the theory of traces in Lipschitz domains (see e.g. 13, Section VI.2]), for $s=1-$ there is a continuous extension operator from $H^{s}(\partial \mathcal{R})$ to $H^{s+1 / 2}(\mathcal{R})$, and its operator norm is bounded by a constant depending only on the Lipschitz regularity of $\mathcal{R}$, hence only on the Lipschitz regularity of $\Omega$. Thus there exists an extension $\Phi \in H^{\frac{3}{2}-}(\mathcal{R})$ of $\left.\varphi_{\varepsilon}\right|_{\partial \mathcal{R}}$ such that

$$
\|\Phi\|_{H^{\frac{3}{2}-}(\mathcal{R})} \lesssim 1+N_{\varepsilon}^{\frac{1}{2}}+M_{\varepsilon}^{\frac{1}{2}}
$$

By Sobolev embedding $H^{\frac{1}{2}-}(\mathcal{R}) \subset L^{4-}(\mathcal{R})$ we deduce the bound

$$
\begin{equation*}
\|\nabla \Phi\|_{L^{q}(\mathcal{R})} \lesssim 1+N_{\varepsilon}^{\frac{1}{2}}+M_{\varepsilon}^{\frac{1}{2}} \tag{21}
\end{equation*}
$$

The constant in the Sobolev embedding depends only on the Lipschitz regularity of $\Omega$ since $\mathcal{R}$ is bi-Lipschitz homeomorphic to the unit ball (with Lipschitz constants depending only on the Lipschitz regularity of $\Omega$ ). Denoting

$$
\psi:=\varphi_{\varepsilon}-\Phi \in H_{0}^{1}(\mathcal{R})
$$

by (17), $\psi$ solves

$$
\Delta \psi=\nabla \cdot\left(\left(1-\rho_{\varepsilon}^{2}\right) \nabla \varphi_{\varepsilon}-\nabla \Phi\right) \quad \text { in } \quad \mathcal{R}
$$

so that elliptic estimates in Lipschitz domains (see e.g. [12, Theorem 0.5] or [17, Theorem 2]) yield

$$
\left\|\nabla \varphi_{\varepsilon}\right\|_{L^{q}(\mathcal{R})} \leq C\left(1+\left\|\left(1-\rho_{\varepsilon}^{2}\right) \nabla \varphi_{\varepsilon}\right\|_{L^{q}(\mathcal{R})}+\|\nabla \Phi\|_{L^{q}(\mathcal{R})}\right)
$$

By Theorem 7. $C\left|1-\rho_{\varepsilon}^{2}\right| \leq \frac{1}{2}$ in $\mathcal{R}$ for $\kappa>0$ small enough. This implies

$$
\left\|\nabla \varphi_{\varepsilon}\right\|_{L^{q}(\mathcal{R})} \lesssim 1+\|\nabla \Phi\|_{L^{q}(\mathcal{R})}
$$

The last term can be estimated by (21) and this proves 18 .
Step 2. An improved local estimate of the potential energy. We will prove the following:
Lemma 12 Let $\Omega \subset \mathbb{R}^{2}$ be a Lipschitz bounded domain. If $u_{\varepsilon}$ satisfies (1) and (4), then

$$
\frac{1}{\varepsilon^{2}} \int_{\mathcal{R}}\left(1-\left|u_{\varepsilon}\right|^{2}\right)^{2} d x \lesssim \varepsilon^{1-}\left(1+N_{\varepsilon}+M_{\varepsilon}\right)\left(1+M_{\varepsilon}\right)^{\frac{1}{2}-}
$$

for every point $x_{0} \in \Omega$ with the associated domain $\mathcal{R}$ in 15 .

[^7]Proof. Multiplying (17) by $1-\rho_{\varepsilon}^{2}$, as $\rho_{\varepsilon} \geq 1 / 2$ in $\mathcal{R}$ (by Theorem 7), integration by parts yields ${ }^{12}$

$$
\begin{aligned}
\frac{1}{2 \varepsilon^{2}} \int_{\mathcal{R}}\left(1-\rho_{\varepsilon}^{2}\right)^{2} d x & \leq \frac{1}{\varepsilon^{2}} \int_{\mathcal{R}} \rho_{\varepsilon}\left(1-\rho_{\varepsilon}^{2}\right)^{2} d x \\
& =-\int_{\mathcal{R}}\left(1-\rho_{\varepsilon}^{2}\right) \Delta \rho_{\varepsilon} d x+\int_{\mathcal{R}} \rho_{\varepsilon}\left(1-\rho_{\varepsilon}^{2}\right)\left|\nabla \varphi_{\varepsilon}\right|^{2} d x \\
& =-\int_{\partial \mathcal{R}}\left(1-\rho_{\varepsilon}^{2}\right) \partial_{\nu} \rho_{\varepsilon} d \mathcal{H}^{1}-2 \int_{\mathcal{R}} \rho_{\varepsilon}\left|\nabla \rho_{\varepsilon}\right|^{2} d x+\int_{\mathcal{R}} \rho_{\varepsilon}\left(1-\rho_{\varepsilon}^{2}\right)\left|\nabla \varphi_{\varepsilon}\right|^{2} d x \\
& \leq\left\|1-\rho_{\varepsilon}^{2}\right\|_{L^{2}(\partial \mathcal{R})}\left\|\partial_{\nu} \rho_{\varepsilon}\right\|_{L^{2}(\partial \mathcal{R})}+2\left\|\nabla \varphi_{\varepsilon}\right\|_{L^{q}(\mathcal{R})}^{2}\left\|1-\rho_{\varepsilon}^{2}\right\|_{L^{\frac{q}{q-2}}(\mathcal{R})} \\
& \lesssim \varepsilon\left(M_{\varepsilon}+N_{\varepsilon}\right)+\varepsilon^{1-}\left(1+N_{\varepsilon}+M_{\varepsilon}\right) M_{\varepsilon}^{\frac{1}{2}-}
\end{aligned}
$$

for $q=4-$, where we used

- (22) and (16) yielding $\left\|1-\rho_{\varepsilon}^{2}\right\|_{L^{2}(\partial \mathcal{R})} \lesssim \varepsilon\left(M_{\varepsilon}+N_{\varepsilon}\right)^{\frac{1}{2}}$;
- (19) yielding $\left\|\partial_{\nu} \rho_{\varepsilon}\right\|_{L^{2}(\partial \mathcal{R})} \lesssim\left(M_{\varepsilon}+N_{\varepsilon}\right)^{\frac{1}{2}}$;
- (18) and the interpolation inequality for $\lambda=\frac{2(q-2)}{q}=1-$

$$
\left\|1-\rho_{\varepsilon}^{2}\right\|_{L^{\frac{q}{q-2}}(\mathcal{R})} \leq\left\|1-\rho_{\varepsilon}^{2}\right\|_{L^{\infty}(\mathcal{R})}^{1-\lambda}\left\|1-\rho_{\varepsilon}^{2}\right\|_{L^{2}(\mathcal{R})}^{\lambda} \stackrel{\sqrt[33]{3}, \sqrt[8]{8}}{\lesssim} \varepsilon^{\lambda} M_{\varepsilon}^{\frac{\lambda}{2}}
$$

yielding the last estimate.
Step 3. Conclusion of Theorem 1. Applying the arguments in the proof of Lemma 11 in the domain $\mathcal{R}=\mathcal{R}_{t}\left(x_{0}\right)$ defined at 15$)$, we find

$$
\left(\left|u_{\varepsilon}\left(x_{0}\right)\right|^{2}-1\right)^{6+} \lesssim \frac{1}{\varepsilon^{2}} \int_{\mathcal{R}}\left(1-\rho_{\varepsilon}^{2}\right)^{2} d x \lesssim \varepsilon^{1-}\left(1+N_{\varepsilon}+M_{\varepsilon}\right)\left(1+M_{\varepsilon}\right)^{\frac{1}{2}-}
$$

The last inequality follows from the previous step. Since $x_{0} \in \Omega$ is arbitrary and the constant depends only on the Lipschitz regularity of $\Omega$, this proves Theorem 1 .

## 4 Optimality of the regime (4)

In this section, we prove Propositions 2 to 5 .
Proof of Proposition 2, Let $\Omega$ be a cone of opening angle $\theta_{0}$ and height 1 , see Figure 4. Consider the point $P_{\varepsilon}$ on the medial axis at distance $s_{\varepsilon}$ from the corner, where

$$
s_{\varepsilon}=\varepsilon^{\mu} \quad \text { with } 0<\mu<1
$$

Set $\alpha=\frac{1+\mu}{2} \in(0,1)$. We also denote by $d_{\varepsilon}$ the distance of $P_{\varepsilon}$ to the boundary $\partial \Omega$. For $\theta_{1}=\theta_{0}+\eta$ (where, possibly lowering $\eta$, we may assume $\eta<\theta_{0}$ ) consider the cone $K_{1}$ of opening $\theta_{1}$ and height 1 centered at $P_{\varepsilon}$ and with the same medial axis. The boundaries of the two cones intersect in two points at a distance $r_{\varepsilon}$ from $P_{\varepsilon}$. It follows that $\Omega \subset B\left(P_{\varepsilon}, r_{\varepsilon}\right) \cup K_{1}\left(\right.$ as $\left.s_{\varepsilon}<r_{\varepsilon}\right)$,

$$
d_{\varepsilon}=s_{\varepsilon} \sin \frac{\theta_{0}}{2} \sim \varepsilon^{\mu} \quad \text { and } \quad r_{\varepsilon}=s_{\varepsilon} \frac{\sin \frac{\theta_{0}}{2}}{\sin \frac{\eta}{2}} \sim \varepsilon^{\mu} .
$$

[^8]Figure 2: The cones $\Omega$ and $K_{1}$ of opening angles $\theta_{0}$ and $\theta_{1}$ respectively.

We consider the following degree-one vortex solution $u_{\varepsilon}$ of (11):

$$
u_{\varepsilon}(x)=f\left(\frac{\left|x-P_{\varepsilon}\right|}{\varepsilon}\right) \frac{x-P_{\varepsilon}}{\left|x-P_{\varepsilon}\right|} \quad \text { for every } \quad x \in \mathbb{R}^{2}
$$

where $P_{\varepsilon}$ is the vortex point (i.e., $u_{\varepsilon}\left(P_{\varepsilon}\right)=0$ ), $f:[0, \infty) \rightarrow[0,1)$ is the smooth radial profile given by the unique solution of

$$
-f^{\prime \prime}-\frac{1}{r} f^{\prime}+\frac{1}{r^{2}} f=f\left(1-f^{2}\right) \quad \text { for every } \quad r \in(0, \infty)
$$

with $f(0)=0$ and $\lim _{r \rightarrow \infty} f(r)=1 ; f$ and $f^{\prime}$ have the following asymptotics for $r \rightarrow \infty$ (see [6, 9])

$$
f(r)=1-\frac{1}{2 r^{2}}-\frac{9}{8 r^{4}}+O\left(r^{-6}\right), \quad f^{\prime}(r)=\frac{1}{r^{3}}+\frac{9}{2 r^{5}}+O\left(r^{-7}\right)
$$

In a point $x \in \mathbb{R}^{2}$ with $\left|x-P_{\varepsilon}\right|=t$, the Ginzburg-Landau energy density is given by

$$
e_{\varepsilon}\left(u_{\varepsilon}(x)\right)=\frac{1}{2}\left(\frac{\left|f^{\prime}\left(\frac{t}{\varepsilon}\right)\right|^{2}}{\varepsilon^{2}}+\frac{\left|f\left(\frac{t}{\varepsilon}\right)\right|^{2}}{t^{2}}\right)+\frac{1}{4 \varepsilon^{2}}\left(1-\left|f\left(\frac{t}{\varepsilon}\right)\right|^{2}\right)^{2}
$$

so that for $t \geq \varepsilon$, we find

$$
\begin{equation*}
e_{\varepsilon}\left(u_{\varepsilon}(x)\right)=\frac{1}{2 t^{2}}+\frac{1}{\varepsilon^{2}} O\left(\frac{\varepsilon^{4}}{t^{4}}\right) \tag{22}
\end{equation*}
$$

Recalling that $r_{\varepsilon} \gg \varepsilon$, we obtain by integrating over $K_{1} \backslash B\left(P_{\varepsilon}, r_{\varepsilon}\right)$ :

$$
\int_{K_{1} \backslash B\left(P_{\varepsilon}, r_{\varepsilon}\right)} e_{\varepsilon}\left(u_{\varepsilon}\right) d x \leq \theta_{1} \int_{r_{\varepsilon}}^{2} t\left(\frac{1}{2 t^{2}}+\frac{1}{\varepsilon^{2}} O\left(\frac{\varepsilon^{4}}{t^{4}}\right)\right) d t \leq \frac{\theta_{1}}{2} \log \frac{2}{r_{\varepsilon}}+O\left(\frac{\varepsilon^{2}}{r_{\varepsilon}^{2}}\right)
$$

In $B\left(P_{\varepsilon}, r_{\varepsilon}\right)$, using (22) and the fact that $f(0)=0$ and $\left|f^{\prime}\right| \lesssim 1$ (in particular, $|f(t)| \lesssim t$ for $t>0$ ), we estimate

$$
\begin{aligned}
\int_{B\left(P_{\varepsilon}, r_{\varepsilon}\right)} e_{\varepsilon}\left(u_{\varepsilon}\right) d x & \leq \pi\left(\int_{0}^{\varepsilon}+\int_{\varepsilon}^{r_{\varepsilon}}\right)\left[\left(\frac{\left|f^{\prime}\left(\frac{t}{\varepsilon}\right)\right|^{2}}{\varepsilon^{2}}+\frac{\left|f\left(\frac{t}{\varepsilon}\right)\right|^{2}}{t^{2}}\right)+\frac{1}{2 \varepsilon^{2}}\left(1-\left|f\left(\frac{t}{\varepsilon}\right)\right|^{2}\right)^{2}\right] t d t \\
& \leq C \int_{0}^{\varepsilon} \frac{t}{\varepsilon^{2}} d t+\pi \log \frac{r_{\varepsilon}}{\varepsilon}+O(1)=\pi \log \frac{r_{\varepsilon}}{\varepsilon}+O(1)
\end{aligned}
$$

As $\Omega \subset B\left(P_{\varepsilon}, r_{\varepsilon}\right) \cup K_{1}$, it follows that the interior energy $M_{\varepsilon}$ is estimated as:

$$
M_{\varepsilon}=\int_{\Omega} e_{\varepsilon}\left(u_{\varepsilon}\right) d x \leq \pi \log \frac{r_{\varepsilon}}{\varepsilon}+\frac{\theta_{1}}{2} \log \frac{2}{r_{\varepsilon}}+O(1) \leq\left(\pi(1-\mu)+\frac{\theta_{1}}{2} \mu\right)|\log \varepsilon|+C
$$

where $C>0$ is a constant depending only on $\eta$ and $\theta_{0}$. Note that for $\mu$ sufficiently close to 1 and $\varepsilon$ small enough, this implies

$$
M_{\varepsilon} \leq\left(\frac{\theta_{0}}{2}+\eta\right)|\log \varepsilon|
$$

To estimate the boundary energy $N_{\varepsilon}$, we write $\partial \Omega=\Gamma_{1} \cup \Gamma_{2}^{+} \cup \Gamma_{2}^{-}$, where $\Gamma_{1}$ is the basis of the cone, and $\Gamma_{2}^{ \pm}$are the two sides of the cone adjacent to its vertex. Since $P_{\varepsilon}$ is at distance $\sim 1$ of $\Gamma_{1}$, it holds

$$
\int_{\Gamma_{1}} e_{\varepsilon}\left(u_{\varepsilon}\right) d \mathcal{H}^{1}=O(1)
$$

On the rest of the boundary, note that for every point $x \in \Gamma_{2}^{ \pm}$that has a distance $s$ from the orthogonal projections of $P_{\varepsilon}$ onto $\Gamma_{2}^{ \pm}$, we have

$$
e_{\varepsilon}\left(u_{\varepsilon}(x)\right)=\frac{1}{2 t^{2}}+\frac{1}{\varepsilon^{2}} O\left(\frac{\varepsilon^{4}}{t^{4}}\right), \quad \text { where } t=\left|x-P_{\varepsilon}\right|=\sqrt{s^{2}+d_{\varepsilon}^{2}}
$$

since $t \geq d_{\varepsilon} \sim \varepsilon^{\mu} \gg \varepsilon$. We can thus estimate

$$
N_{\varepsilon} \leq 2 \int_{-\infty}^{\infty}\left(\frac{1}{2\left(s^{2}+d_{\varepsilon}^{2}\right)}+C \frac{\varepsilon^{2}}{\left(s^{2}+d_{\varepsilon}^{2}\right)^{2}}\right) d s+O(1) \lesssim \frac{1}{d_{\varepsilon}}+\frac{\varepsilon^{2}}{d_{\varepsilon}^{3}} \lesssim \frac{1}{s_{\varepsilon}} \sim \frac{1}{\varepsilon^{\mu}} \ll \frac{1}{\varepsilon^{\alpha}}
$$

as $\alpha$ was chosen such that $\alpha=\frac{1+\mu}{2}<1$. So (4) holds with $\kappa=\frac{\theta_{0}}{2}+\eta$, while $u_{\varepsilon}\left(P_{\varepsilon}\right)=0$.
Remark 3 Applying the construction in the proof of Proposition 2 to a half-space domain, we deduce that a necessary condition in order that Theorem 1 holds true is given by $\kappa \leq \frac{\pi}{2}$ in (4) (even for smooth domains $\Omega$ ).

Proof of Proposition 3. Let $f:[0, \infty) \rightarrow[0,1]$ be a smooth function with $f(0)=0, f(r)=1$ for $r \geq 1$ and $\left|f^{\prime}(r)\right| \leq C$. Let $x_{0} \in \partial \Omega$ and consider $v_{\varepsilon}(x)=f\left(\frac{x-x_{0}}{\varepsilon}\right)$ for every $x \in \mathbb{R}^{2}$. Let $g_{\varepsilon}=$ $\left(v_{\varepsilon}, 0\right)$ on $\partial \Omega$ and let $u_{\varepsilon}$ be a minimizer of the Ginzburg-Landau energy with Dirichlet boundary conditions $g_{\varepsilon}$, in particular, $u_{\varepsilon}\left(x_{0}\right)=g_{\varepsilon}\left(x_{0}\right)=0$. Then $u_{\varepsilon}$ satisfies (1) and (by minimality) $M_{\varepsilon} \leq E_{\varepsilon}\left(v_{\varepsilon} ; \Omega\right) \lesssim 1$ while $N_{\varepsilon} \lesssim \frac{1}{\varepsilon}$.
Proof of Proposition 4. Since $\Omega$ is smooth, bounded and simply connected, upon applying a conformal diffeomorphism we assume $\Omega=B(0,1)$ is the unit disk ${ }^{13}$ Our example is strongly inspired by [1, Example 1] and [2, Lemma 4.1]. For $\eta>0$ small we consider

$$
v_{\eta}(z)=\frac{z-(1-\eta)}{1-(1-\eta) z} \quad \text { for } z \in B(0,1) \subset \mathbb{C}
$$

[^9]and denote by $g_{\eta}$ its boundary datum $g_{\eta}(\theta)=v_{\eta}\left(e^{i \theta}\right)$, which satisfies $\left|g_{\eta}\right|=1$ on $\partial B(0,1)$. As explained in [2, Lemma 4.1], the map $v_{\eta}$ satisfies
$$
\frac{1}{2} \int_{B(0,1)}\left|\nabla v_{\eta}\right|^{2} d x=\pi, \quad \text { and } \operatorname{deg}\left(v_{\eta}, \partial B(0,1)\right)=1
$$

Lengthy but direct computations show that for $\theta \in(-\pi, \pi)$ we have

$$
\left|g_{\eta}^{\prime}(\theta)\right|^{2}=\frac{(2-\eta)^{2}}{\eta^{2}} \frac{1}{\left(1+2 \frac{1-\eta}{\eta^{2}}(1-\cos \theta)\right)^{2}}
$$

Moreover $1-\cos \theta \geq \frac{2}{\pi^{2}} \theta^{2}$ for $\theta \in(-\pi, \pi)$, and therefore, for small $\eta$,

$$
\begin{aligned}
\int_{-\pi}^{\pi}\left|g_{\eta}^{\prime}(\theta)\right|^{2} d \theta & \lesssim \frac{1}{\eta^{2}} \int_{-\pi}^{\pi} \frac{d \theta}{\left(1+\frac{\theta^{2}}{\eta^{2}}\right)^{2}}=\frac{1}{\eta} \int_{-\frac{\pi}{\eta}}^{\frac{\pi}{\eta}} \frac{d t}{\left(1+t^{2}\right)^{2}} \\
& \lesssim \frac{1}{\eta}
\end{aligned}
$$

For $0<r<1$ and $\theta \in(-\pi, \pi)$, setting $a=1-\eta$ we have

$$
1-\left|v_{\eta}\left(r e^{i \theta}\right)\right|^{2}=\left(1-a^{2}\right) \frac{1-r^{2}}{\left(1+a^{2} r^{2}-2 a r \cos \theta\right)}
$$

In order to estimate $\int\left(1-\left|v_{\eta}\right|^{2}\right)^{2}$ we first compute

$$
I:=\int_{-\pi}^{\pi} \frac{d \theta}{\left(1+a^{2} r^{2}-2 a r \cos \theta\right)^{2}}
$$

The change of variable $x=\tan \frac{\theta}{2}$ gives $d \theta=2 d x /\left(1+x^{2}\right)$ and $\cos \theta=\left(1-x^{2}\right) /\left(1+x^{2}\right)$, so

$$
\begin{aligned}
I & =2 \int_{-\infty}^{\infty} \frac{1+x^{2}}{\left((1-a r)^{2}+(1+a r)^{2} x^{2}\right)^{2}} d x \\
& =\frac{2}{(1+a r)^{4}} \int_{-\infty}^{\infty} \frac{1+x^{2}}{\left(A^{2}+x^{2}\right)^{2}} d x, \quad A:=\frac{1-a r}{1+a r}
\end{aligned}
$$

We have

$$
\begin{aligned}
\int_{-\infty}^{\infty} \frac{1+x^{2}}{\left(A^{2}+x^{2}\right)^{2}} d x & =\int_{-\infty}^{\infty} \frac{d x}{A^{2}+x^{2}}+\left(1-A^{2}\right) \int_{-\infty}^{\infty} \frac{d x}{\left(A^{2}+x^{2}\right)^{2}} \\
& =\frac{1}{A} \int_{-\infty}^{\infty} \frac{d t}{1+t^{2}}+\left(1-A^{2}\right) \frac{1}{A^{3}} \int_{-\infty}^{\infty} \frac{d t}{\left(1+t^{2}\right)^{2}} \\
& =\frac{1}{A}\left(\pi+\frac{1-A^{2}}{A^{2}} \frac{\pi}{2}\right)=\frac{\pi}{2} \frac{1+A^{2}}{A^{3}}
\end{aligned}
$$

Since $1+a r \geq 1$, plugging this back into $I$ yields

$$
I=2 \pi \frac{1+a^{2} r^{2}}{(1+a r)^{3}} \frac{1}{(1-a r)^{3}} \leq \frac{2 \pi}{(1-a r)^{3}}
$$

We deduce

$$
\begin{aligned}
\int_{B(0,1)}\left(1-\left|v_{\eta}\right|^{2}\right)^{2} d x & =\left(1-a^{2}\right)^{2} \int_{0}^{1}\left(1-r^{2}\right)^{2} I r d r \\
& \lesssim \eta^{2} \int_{0}^{1} \frac{(1-r)^{2}}{(1-a r)^{3}} d r=\eta^{2} \int_{0}^{1} \frac{t^{2}}{(a t+\eta)^{3}} d t \\
& =\frac{1}{\eta} \int_{0}^{1} \frac{t^{2}}{\left(\frac{a}{\eta} t+1\right)^{3}} d t=\frac{\eta^{2}}{a^{3}} \int_{0}^{\frac{a}{\eta}} \frac{s^{2}}{(s+1)^{3}} d s \\
& \lesssim \eta^{2} \log \frac{1}{\eta}
\end{aligned}
$$

In particular,

- choosing $\eta=\varepsilon /|\log \varepsilon|^{\frac{1}{2}}$ and $u_{\varepsilon}$ minimizing the Ginzburg-Landau energy with Dirichlet condition $u_{\varepsilon}=g_{\eta}$ on $\partial B(0,1)$, we have that $u_{\varepsilon}$ is of modulus one and degree one on $\partial B(0,1)$ while $M_{\varepsilon} \lesssim 1$ and $N_{\varepsilon} \lesssim \frac{|\log \varepsilon|^{\frac{1}{2}}}{\varepsilon} ;$
- choosing $\eta:=\frac{\varepsilon \sqrt{\kappa}}{L}$ with $L>0$ big enough and $u_{\varepsilon}$ minimizing the Ginzburg-Landau energy with Dirichlet condition $u_{\varepsilon}=g_{\eta}$ on $\partial B(0,1)$, we have that $u_{\varepsilon}$ is of modulus one and degree one on $\partial B(0,1)$ while $M_{\varepsilon} \leq \kappa|\log \varepsilon|$ and $N_{\varepsilon} \lesssim \frac{1}{\varepsilon}$.

Proof of Proposition 5. Upon locally flattening the boundary and rescaling the domain (thus only introducing multiplicative constants in all estimates), we may assume that $\Omega$ is as in Example 1, i.e. it contains the upper half unit ball:

$$
\Omega \cap B(0,1)=\left\{x=\left(x_{1}, x_{2}\right) \in B(0,1): x_{2}>0\right\}
$$

As in Example 1, for $\eta=\eta(\varepsilon) \ll \varepsilon$ we consider the boundary data $g_{\varepsilon}: \partial \Omega \rightarrow \mathbb{S}^{1}$ such that $g_{\varepsilon}(x)=e^{i \phi_{\varepsilon}}$ with

$$
\phi_{\varepsilon}(x)= \begin{cases}0 & \text { if } x \in \partial \Omega \backslash B(0, \eta) \\ \pi\left(1-\frac{\left|x_{1}\right|}{\eta}\right) & \text { if } x=\left(x_{1}, x_{2}\right) \in \partial \Omega \cap B(0, \eta)\end{cases}
$$

As in Example 1 we then have that $N_{\varepsilon} \sim \frac{1}{\eta}$ and any map $u_{\varepsilon}$ minimizing $E_{\varepsilon}(\cdot ; \Omega)$ with Dirichlet boundary data $u_{\varepsilon}=g_{\varepsilon}$ on $\partial \Omega$ satisfies $M_{\varepsilon} \lesssim 1$.

It remains to show that

$$
\begin{equation*}
\sup _{\Omega}\left|1-\left|u_{\varepsilon}\right|^{2}\right| \geq \frac{1}{2} \quad \text { for } \varepsilon \ll 1 \tag{23}
\end{equation*}
$$

The idea is to use the decomposition $u_{\varepsilon}=v_{\varepsilon}+w_{\varepsilon}$ with

$$
\left\{\begin{array} { r r r } 
{ - \Delta v _ { \varepsilon } } & { = \frac { 1 } { \varepsilon ^ { 2 } } ( 1 - | u _ { \varepsilon } | ^ { 2 } ) u _ { \varepsilon } } & { \text { in } \Omega , } \\
{ v _ { \varepsilon } } & { = 0 } & { \text { on } \partial \Omega , }
\end{array} \quad \text { and } \quad \left\{\begin{array}{rrr}
\Delta w_{\varepsilon}=0 & \text { in } \Omega \\
w_{\varepsilon}=g_{\varepsilon} & \text { on } \partial \Omega
\end{array}\right.\right.
$$

(see also the proof of Lemma 3 in [7]).
The maximum principle can be used to see that $\left|w_{\varepsilon}\right| \leq 1$ and $\left|u_{\varepsilon}\right| \leq 1$ in $\Omega$. Indeed, since $-\Delta\left|w_{\varepsilon}\right|^{2}=-2\left|\nabla w_{\varepsilon}\right|^{2} \leq 0$ in $\Omega$ and $\left|w_{\varepsilon}\right|=1$ on $\partial \Omega$, the maximal principle implies that $\left|w_{\varepsilon}\right| \leq 1$ in $\Omega$. Moreover, recalling that $\tilde{\rho}_{\varepsilon}=1-\left|u_{\varepsilon}\right|^{2}$ satisfies

$$
-\Delta \tilde{\rho}_{\varepsilon}+\frac{2}{\varepsilon^{2}}\left|u_{\varepsilon}\right|^{2} \tilde{\rho}_{\varepsilon}=2\left|\nabla u_{\varepsilon}\right|^{2} \geq 0 \quad \text { in } \quad \Omega
$$

and $\tilde{\rho}_{\varepsilon}=0$ on $\partial \Omega$, the maximum principle ensures that $\tilde{\rho}_{\varepsilon} \geq 0$ in $\Omega$, i.e. $\left|u_{\varepsilon}\right| \leq 1$ in $\Omega$.
We deduce that $\left|v_{\varepsilon}\right| \leq 2$ in $\Omega$. Using this together with the equation satisfied by $v_{\varepsilon}$, and the interpolation inequality 3

$$
\left\|\nabla v_{\varepsilon}\right\|_{L^{\infty}(\Omega)} \lesssim\left\|v_{\varepsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{1}{2}}\left\|\Delta v_{\varepsilon}\right\|_{L^{\infty}(\Omega)}^{\frac{1}{2}}
$$

we find that $\left\|\nabla v_{\varepsilon}\right\|_{L^{\infty}(\Omega)} \lesssim \frac{1}{\varepsilon}$. In particular, since $v_{\varepsilon}=0$ on $\partial \Omega$, we deduce that $\left|v_{\varepsilon}\right| \lesssim \frac{\eta}{\varepsilon} \ll 1$ in $\Omega \cap B(0,2 \eta)$. As a consequence we have

$$
\left.\sup _{\Omega \cap B(0,2 \eta)}| | u_{\varepsilon}\right|^{2}-\left|w_{\varepsilon}\right|^{2} \mid \ll 1
$$

and to prove 23 it suffices to show that

$$
\begin{equation*}
\left|w_{\varepsilon}(0, \eta)\right|^{2}<\frac{1}{2} \quad \text { for } \varepsilon \ll 1 \tag{24}
\end{equation*}
$$

To this end we rescale $w_{\varepsilon}$, setting $\tilde{w}_{\eta}(x)=w_{\varepsilon}(\eta x)$ so that

$$
\begin{aligned}
& \begin{cases}\Delta \tilde{w}_{\eta}=0 & \text { in } B\left(0, \frac{1}{\eta}\right) \cap\left\{x_{2}>0\right\} \\
\tilde{w}_{\eta}=e^{i \tilde{\phi}} & \text { on } B\left(0, \frac{1}{\eta}\right) \cap\left\{x_{2}=0\right\}\end{cases} \\
& \text { where } \tilde{\phi}\left(x_{1}, 0\right)= \begin{cases}0 & \text { if }\left|x_{1}\right|>1 \\
\pi\left(1-\left|x_{1}\right|\right) & \text { if }\left|x_{1}\right| \leq 1\end{cases}
\end{aligned}
$$

Since $\left|\tilde{w}_{\eta}\right| \leq 1$ and $\tilde{\phi}$ is Lipschitz, elliptic estimates ensure that $\tilde{w}_{\eta}$ is bounded in $C_{l o c}^{0, \alpha}\left(\left\{x_{2} \geq 0\right\}\right)$ for any $\alpha \in(0,1)$ and therefore admits a subsequence converging locally uniformly to a map $\tilde{w}_{0}:\left\{x_{2} \geq 0\right\} \rightarrow \mathbb{C}$ which solves

$$
\left\{\begin{array}{cc}
\Delta \tilde{w}_{0}=0 \quad \text { in }\left\{x_{2}>0\right\} \\
\tilde{w}_{0}=e^{i \tilde{\phi}} \quad \text { on }\left\{x_{2}=0\right\}
\end{array}\right.
$$

and satisfies $\left|\tilde{w}_{0}\right| \leq 1$. This system has a unique bounded solution, given by the Poisson formula

$$
\tilde{w}_{0}\left(x_{1}, x_{2}\right)=\frac{x_{2}}{\pi} \int_{-\infty}^{\infty} \frac{e^{i \tilde{\phi}(t, 0)}}{\left(x_{1}-t\right)^{2}+x_{2}^{2}} d t
$$

In particular no subsequence is needed for the locally uniform convergence, and we have

$$
w_{\varepsilon}(0, \eta)=\tilde{w}_{\eta}(0,1) \longrightarrow \tilde{w}_{0}(0,1) \quad \text { as } \varepsilon \rightarrow 0
$$

Using the explicit expression of $\tilde{\phi}$ we compute

$$
\begin{aligned}
\tilde{w}_{0}(0,1) & =\frac{2}{\pi}\left(\int_{0}^{1} \frac{e^{i \pi(1-t)}}{1+t^{2}} d t+\int_{1}^{\infty} \frac{1}{1+t^{2}} d t\right) \\
& =\frac{2}{\pi} \int_{0}^{1} \frac{1-e^{-i \pi t}}{1+t^{2}} d t
\end{aligned}
$$

It can be checked that

$$
\left|\int_{0}^{1} \frac{1-e^{-i \pi t}}{1+t^{2}} d t\right| \leq 1
$$

and we infer that

$$
\lim _{\varepsilon \rightarrow 0}\left|w_{\varepsilon}(0, \eta)\right|^{2} \leq \frac{4}{\pi^{2}}<\frac{1}{2}
$$

which implies (24).

[^1]:    ${ }^{1}$ We write $a \ll b$ if $\frac{a}{b} \rightarrow 0$, and $a \lesssim b$ if $\frac{a}{b}$ is bounded by a universal constant.
    ${ }^{2}$ We denote by $a+$ (resp. $a-$ ) any number strictly bigger than $a$ (resp. strictly smaller than $a$ ) that one can think of as close to $a$. The constants in inequalities involving $a+$ or $a$ - may depend on the choice of these numbers.
    ${ }^{3}$ In fact, $C>0$ depends only on the lowest angle and lowest radius of interior and exterior cones at any point of the Lipschitz boundary $\partial \Omega$.
    ${ }^{4}$ In general, $\partial \Omega$ is not connected; the definition of the degree is coherent with the choice of the orientation $\tau=\nu^{\perp}$ given by the outer normal field $\nu$.

[^2]:    ${ }^{5}$ We write $a \sim b$ if $a \lesssim b$ and $b \lesssim a$.

[^3]:    ${ }^{6}$ For the more general energy 5, only the estimate $F(s) \gtrsim(1-s)^{2}$ is needed, which is a consequence of $(s-1) F^{\prime}(s) \gtrsim(1-s)^{2}$ and $F(1)=0$.

[^4]:    ${ }^{7}$ This argument adapts to critical points of the general energy (5), provided $F^{\prime}(s) \geq 0$ for $s \geq 1$, see e.g. [15, Lemma 8.3].
    ${ }^{8}$ For the general energy (5) this argument only uses the fact that $F$ is $C^{1}$ and the validity of a uniform upper bound $\left\|u_{\varepsilon}\right\|_{\infty} \lesssim 1$, implied e.g. by 8 which is valid as soon as $F^{\prime}(s) \geq 0$ for $s \geq 1$.

[^5]:    ${ }^{9}$ In the context of the general energy (5), we need only the assumption that $F \in C^{1}$.

[^6]:    ${ }^{10}$ For the general energy 5 we only need here $(s-1)^{2} \lesssim F(s)$.

[^7]:    ${ }^{11}$ For the general energy (5), no modification is required for this step since the equation satisfied by $\varphi_{\varepsilon}$ stays the same.

[^8]:    ${ }^{12}$ For the general energy 5 , this estimate holds thanks to the assumption $(s-1) F^{\prime}(s) \gtrsim(s-1)^{2}$ for $s \geq 0$.

[^9]:    ${ }^{13}$ Only the bulk energy changes and is bounded (up to a multiplicative constant depending on $\Omega$ ) by the new bulk energy in the disk $B(0,1)$.
